Terraform Registry - Use Publicly Available Modules

The Terraform Registry hosts a broad collection of publicly available Terraform modules for configuring many kinds of common infrastructure.

Modules Demo 1

These modules are free to use, and Terraform can download them automatically if you specify the appropriate source and version in a module call block.

```
# Module: VPC
module "vpc" {
    source  = "terraform-google-modules/network/google"
    version = "~> 9.1"

    project_id    = var.gcp_project
    network_name = "${local.name}-vpc"
    routing_mode = "GLOBAL"
    subnets = [
        {
            subnet_name      = "${local.name}-${var.gcp_region1}-subnet"
            subnet_ip       = "10.128.0.0/20"
            subnet_region   = var.gcp_region1
        }
    ]
}
```

Build a Local Terraform Module

Modules
Demo 2

Build a Local Terraform Module
and call it from Root Module and
Test

Root Module

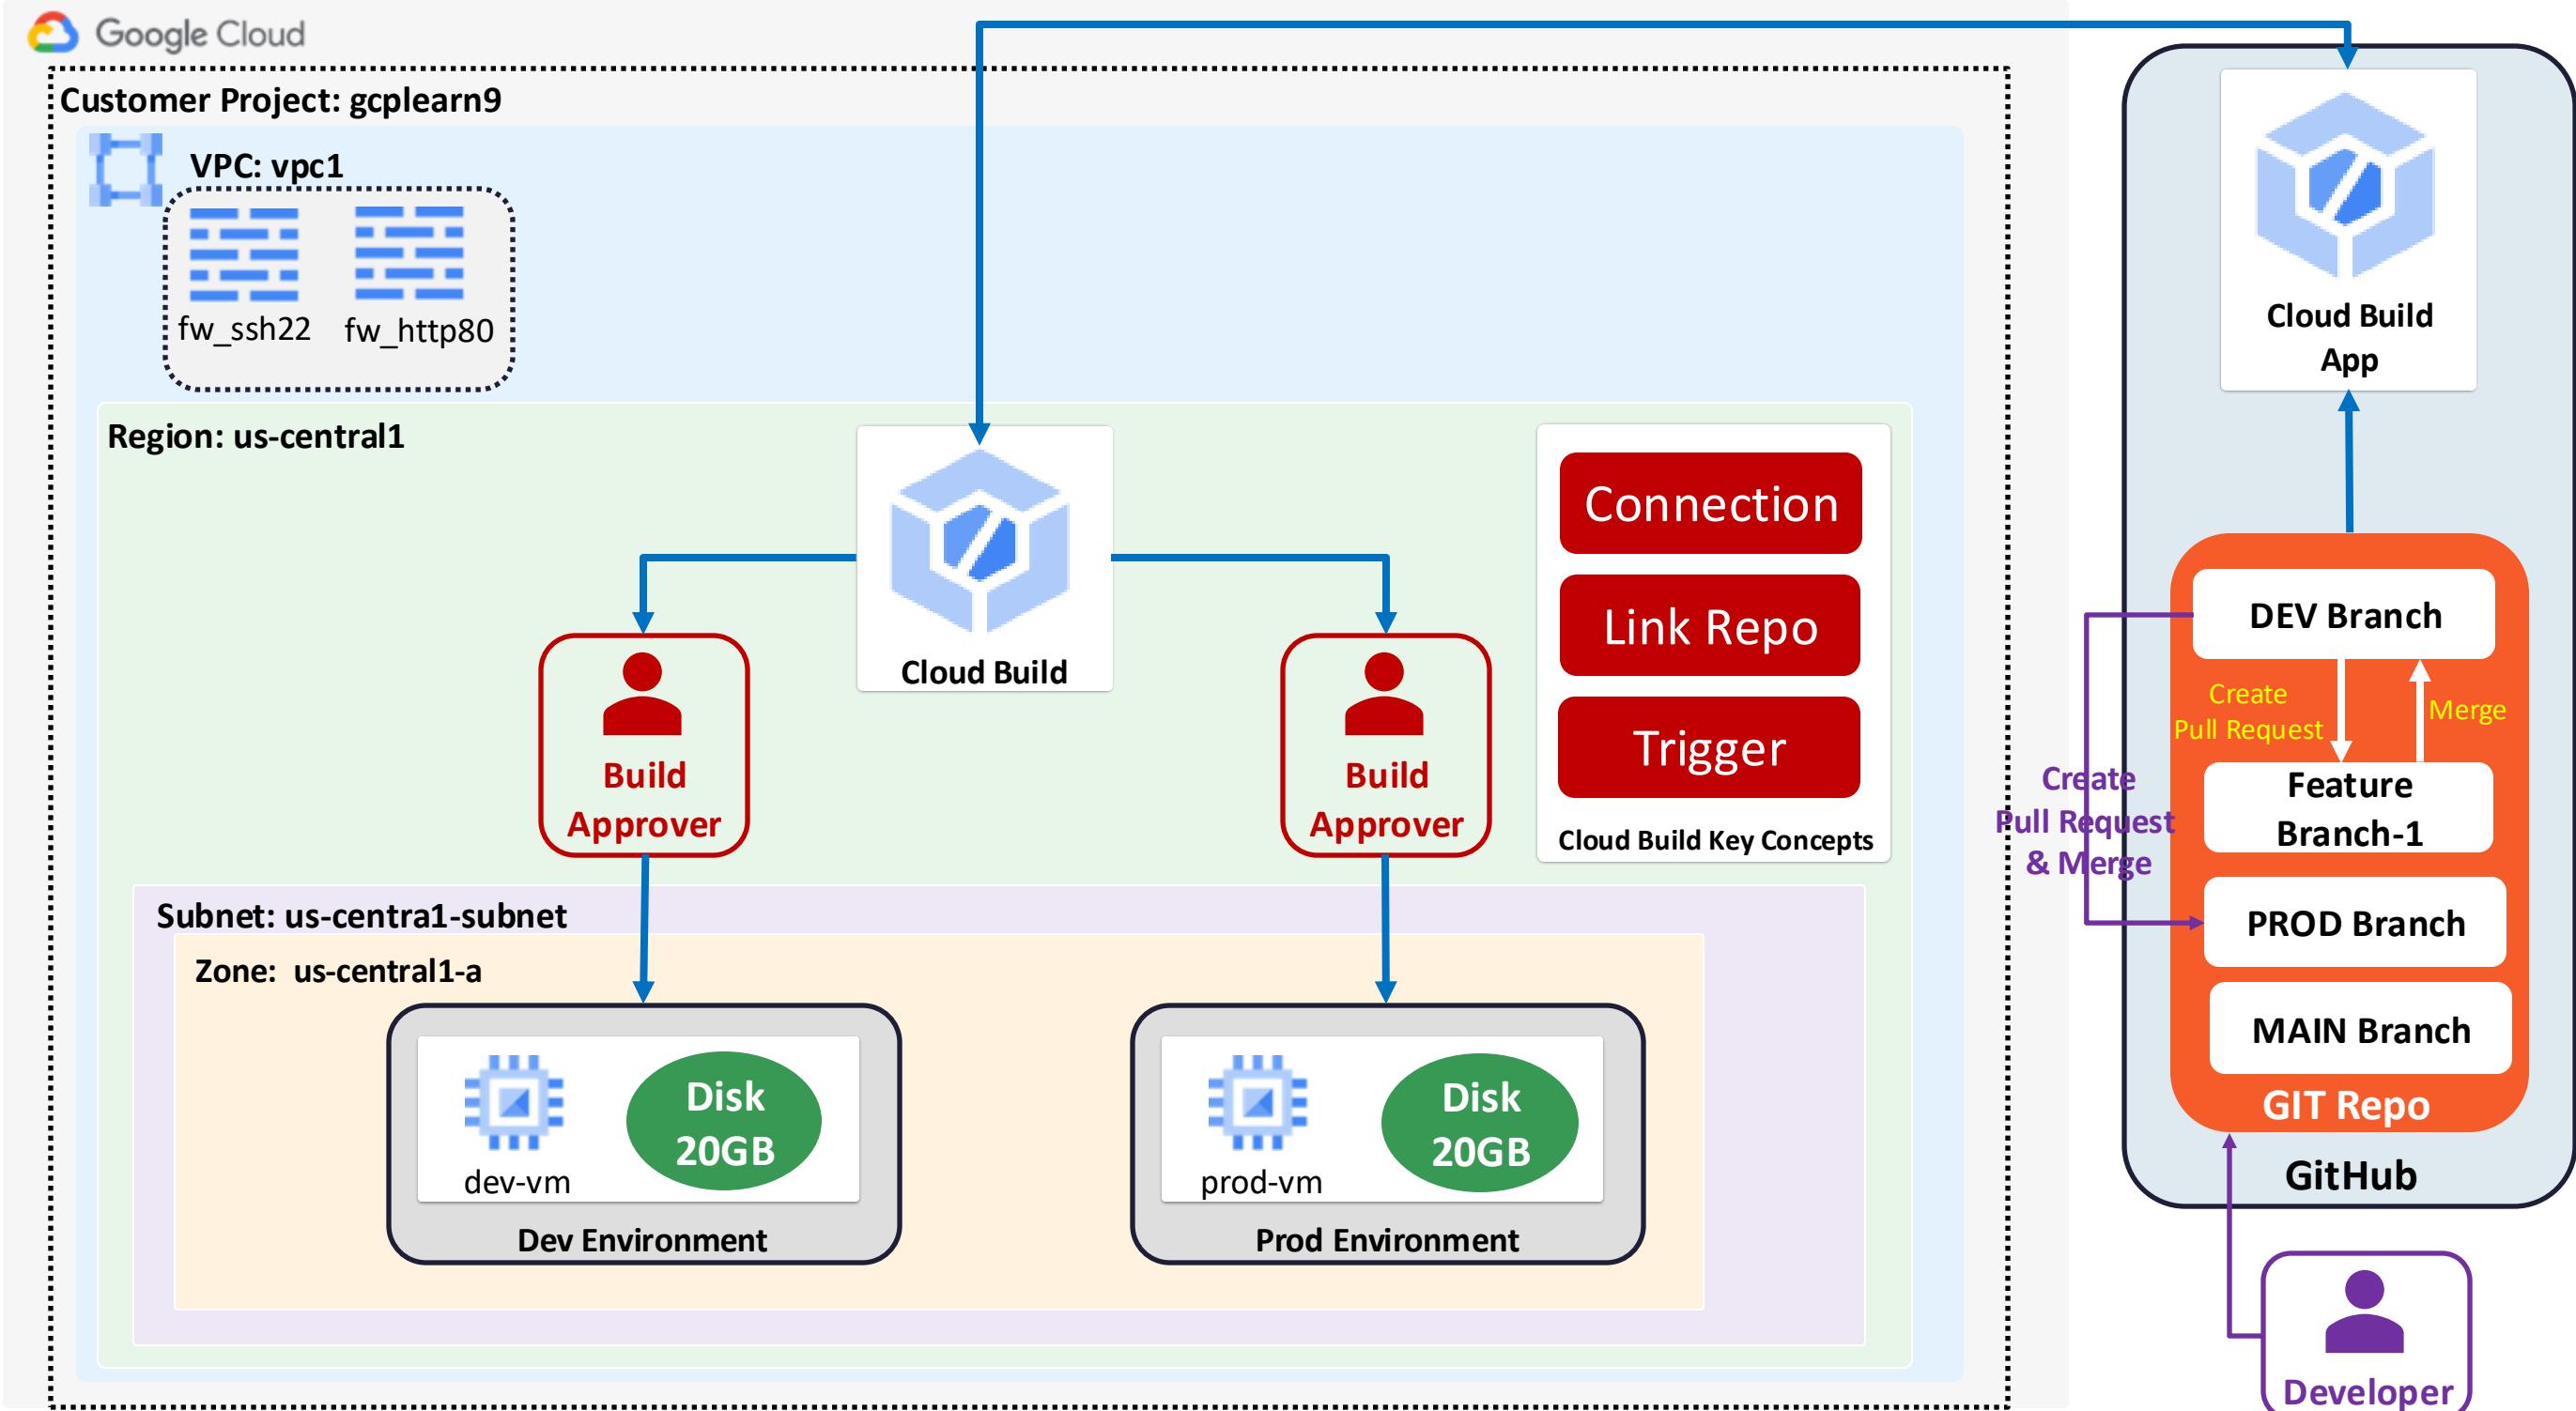

```
└── terraform-manifests
    ├── c1-versions.tf
    ├── c2-variables.tf
    ├── c3-locals.tf
    ├── c4-vpc.tf
    ├── c5-firewalls.tf
    └── c6-vminstance.tf
        └── c7-outputs.tf
    └── terraform.tfvars
```

Call VM Instance child module in
Root Module

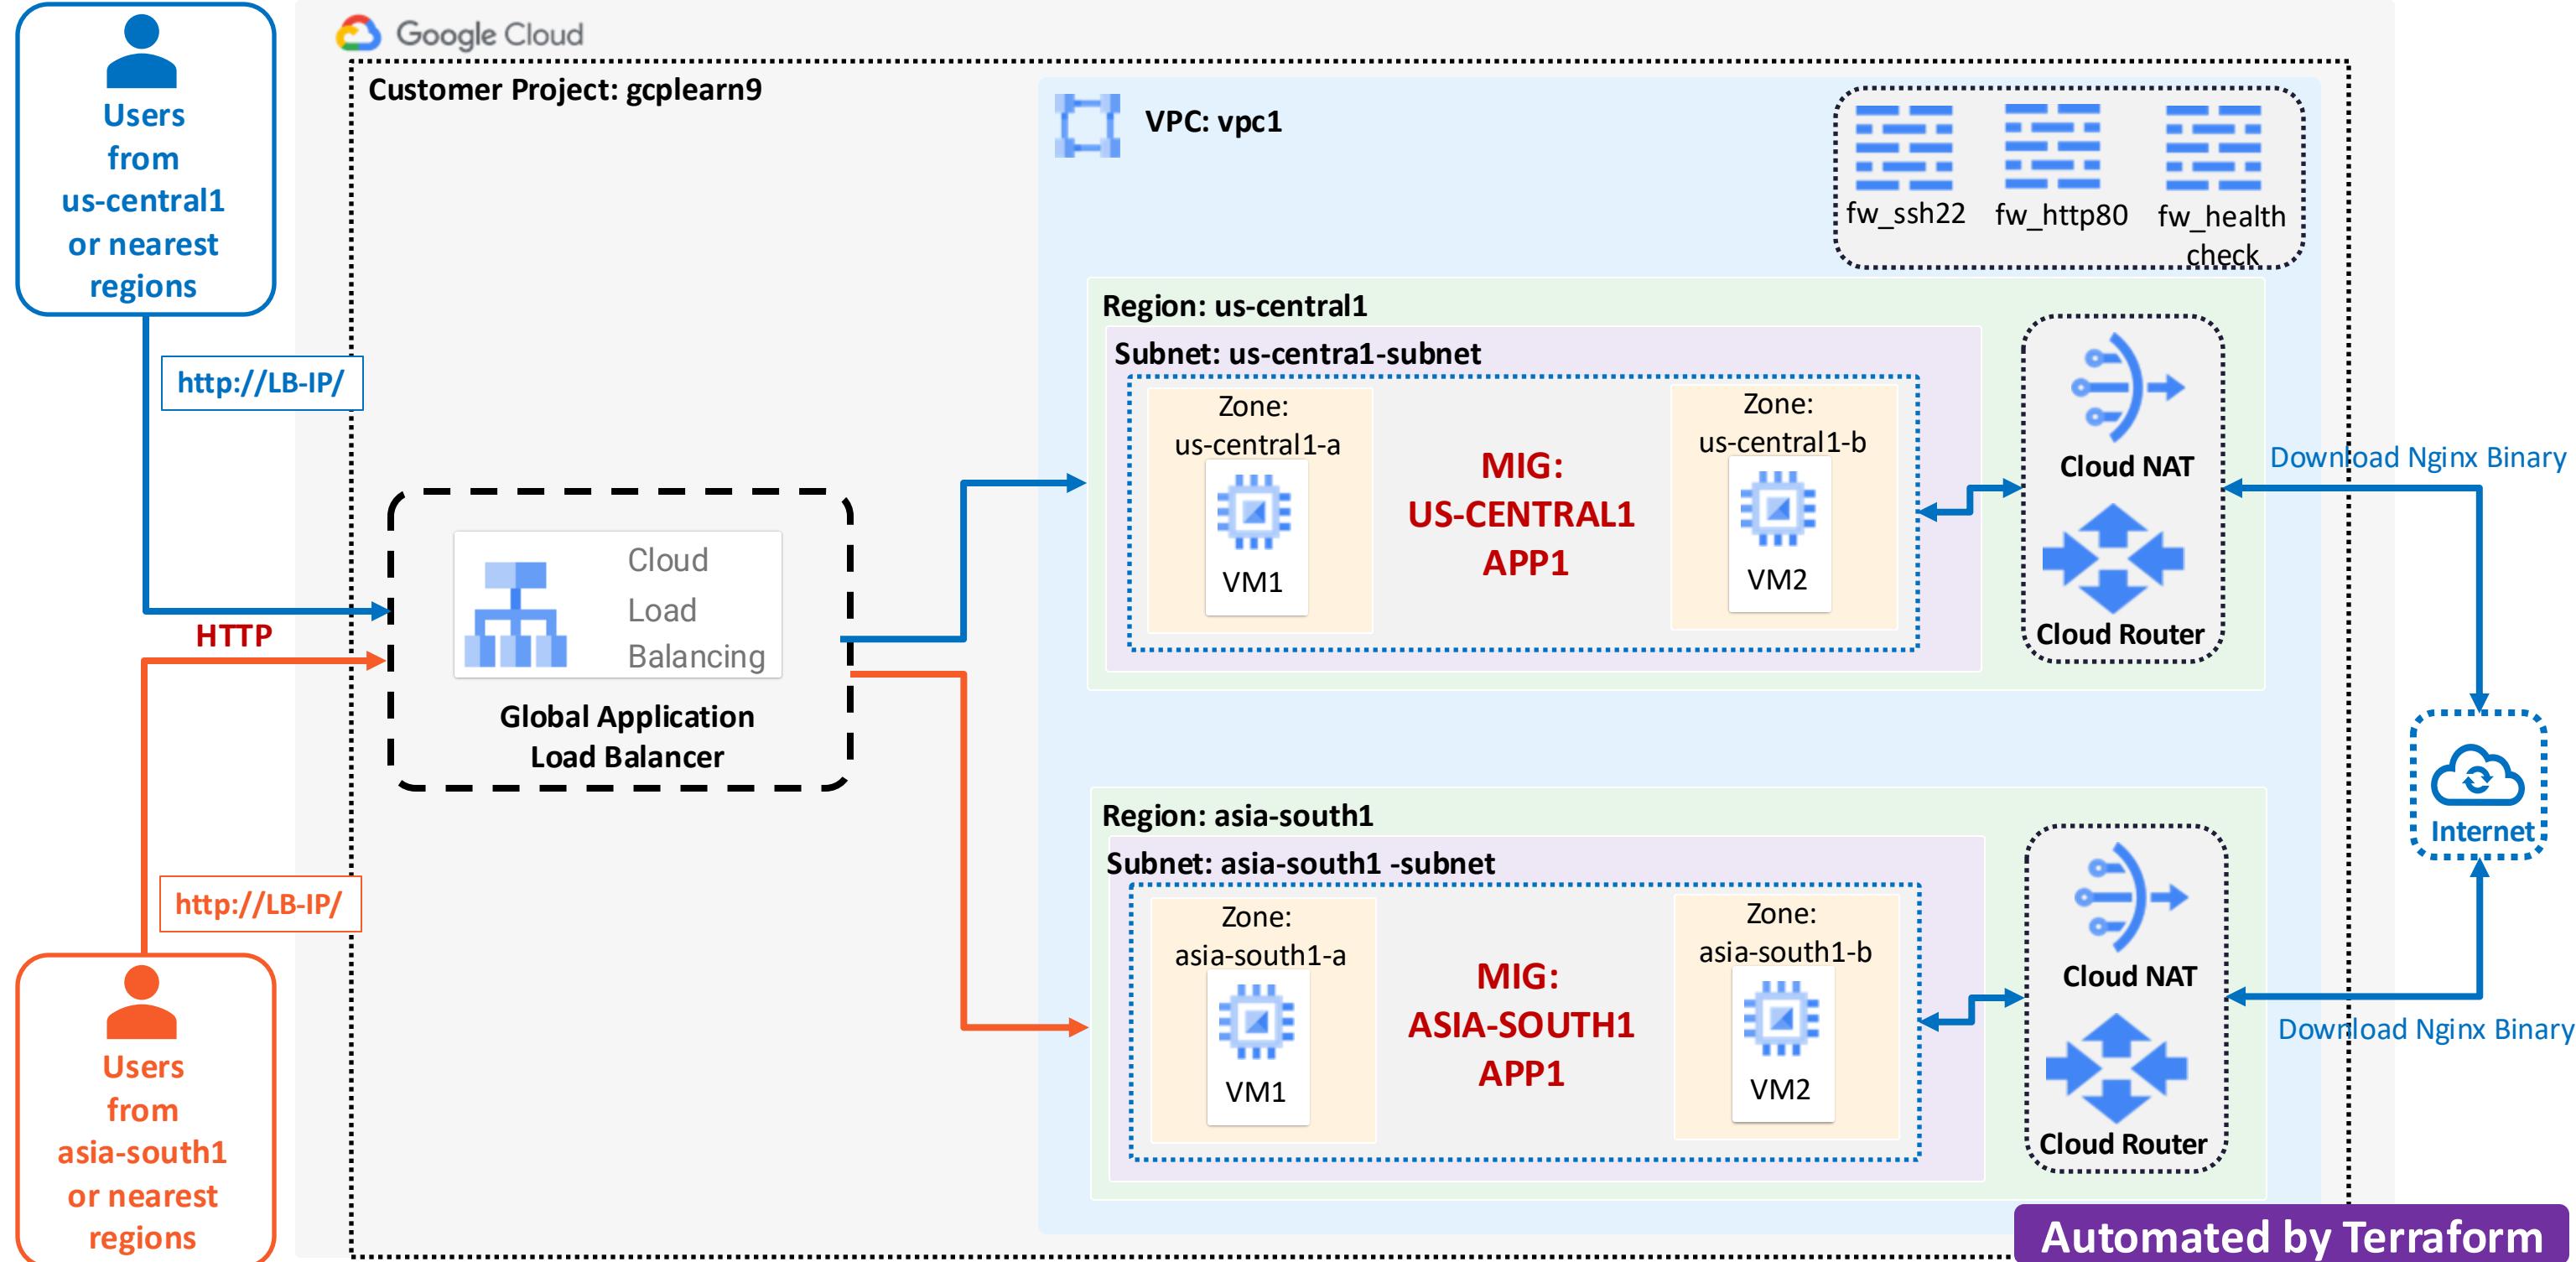

Child Module

```
└── 29-Terraform-Build-Custom-Module
    └── modules/vminstance
        ├── app1-webserver-install.sh
        ├── main.tf
        ├── outputs.tf

plan

apply

destroy

terraform init

terraform validate

terraform plan

terraform apply

terraform destroy

Terraform Workflow

1

init

- Used to **Initialize** a working directory containing terraform config files
- This is the first command that should be run after writing a new Terraform configuration
- Downloads **Providers**

2

validate

- Validates the terraform configurations files in that respective directory to ensure they are **syntactically valid** and **internally consistent**.

3

plan

- Creates an **execution plan**
- Terraform performs a refresh and determines what actions are necessary to achieve the **desired state** specified in configuration files

4

apply

- Used to apply the changes required to reach the **desired state** of the configuration.
- By default, apply scans the current directory for the configuration and applies the changes appropriately.

5

destroy

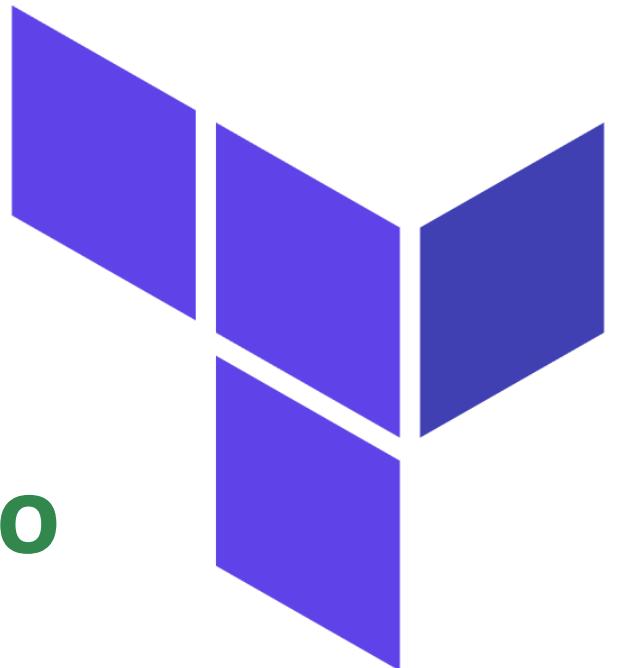

- Used to destroy the Terraform-managed infrastructure
- This will ask for confirmation before destroying.

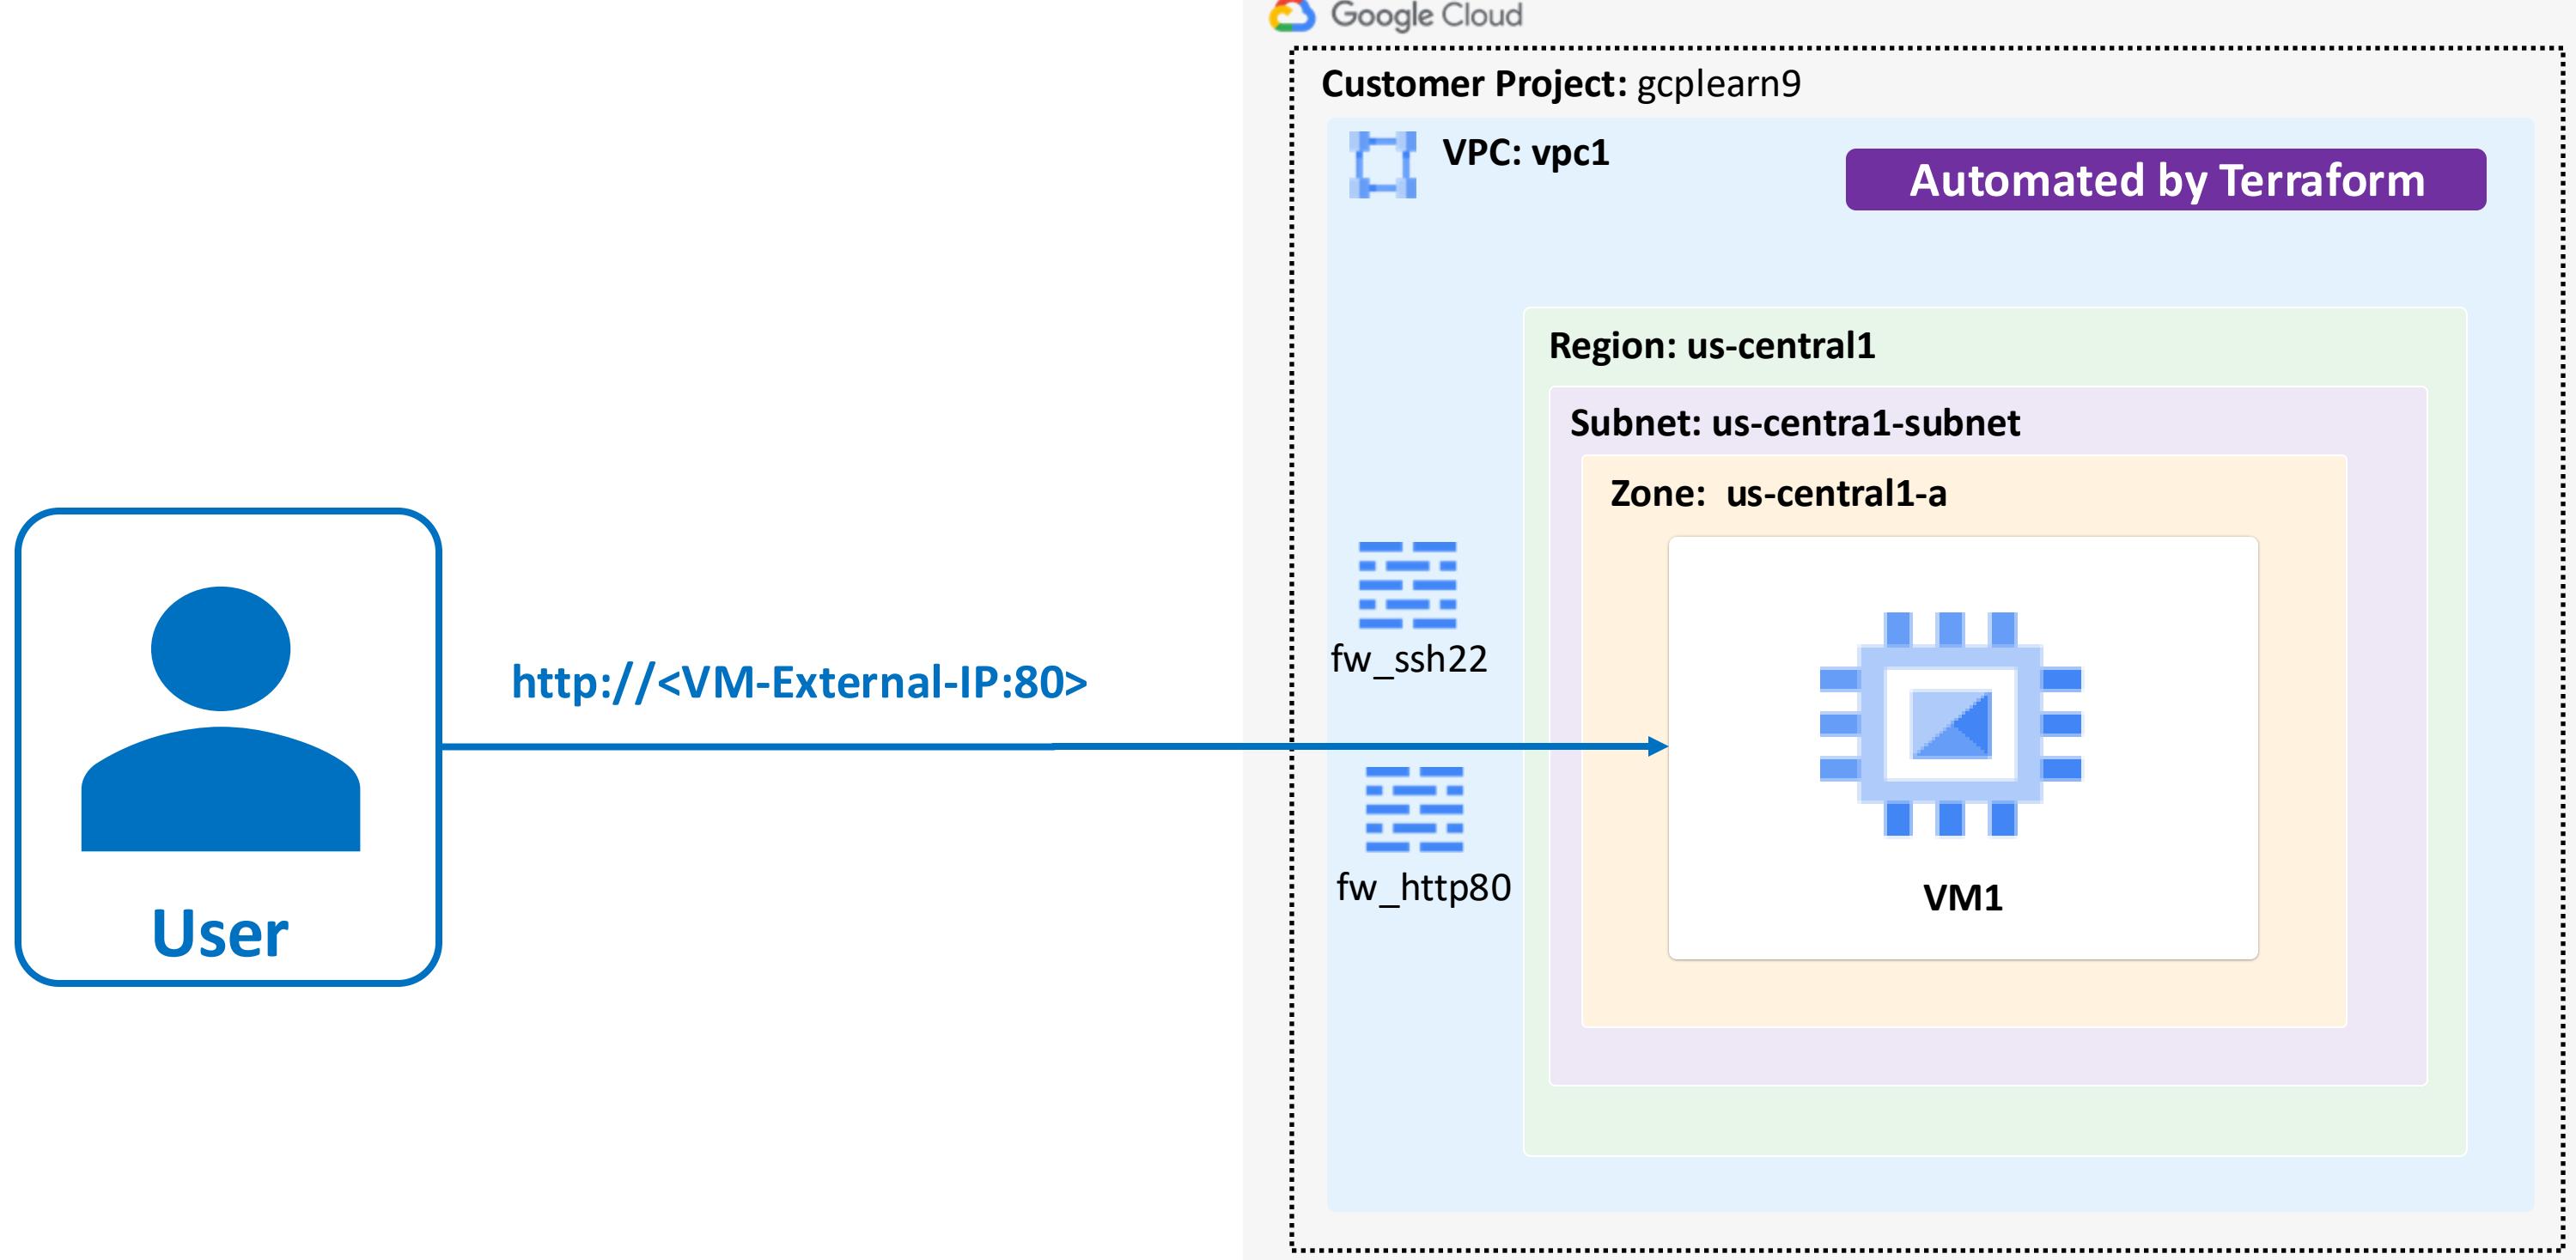

Demo

Terraform

What are we going
to automate as part of this demo
using
Terraform?

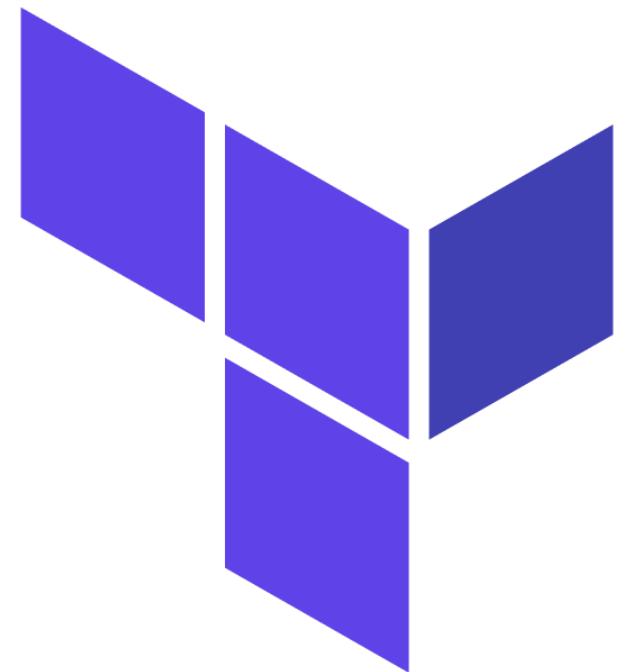

Terraform Language Basics

Demo

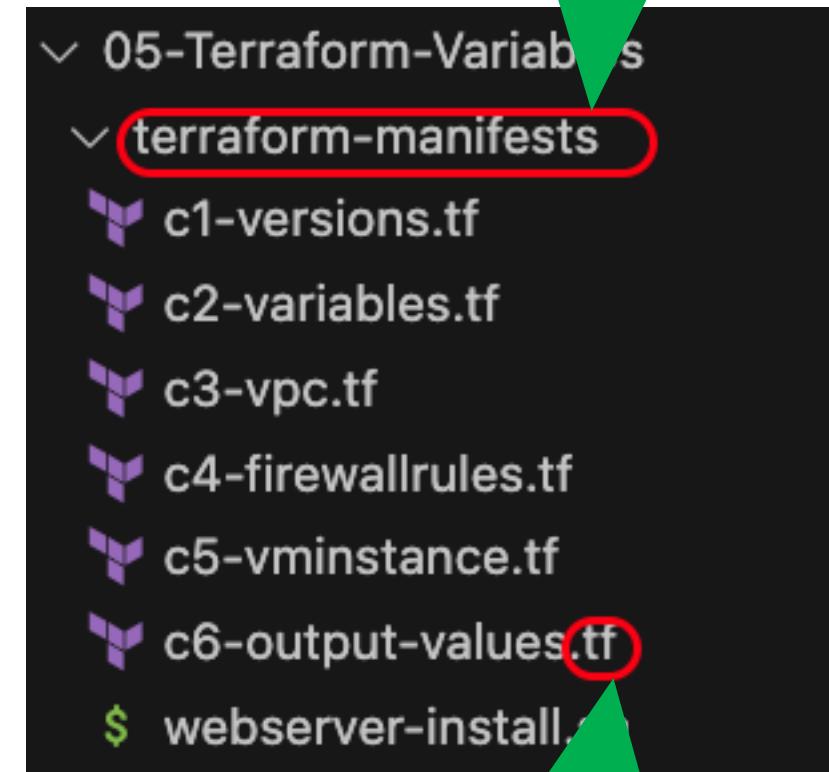

Terraform Language Basics

Terraform Language Basics - Files

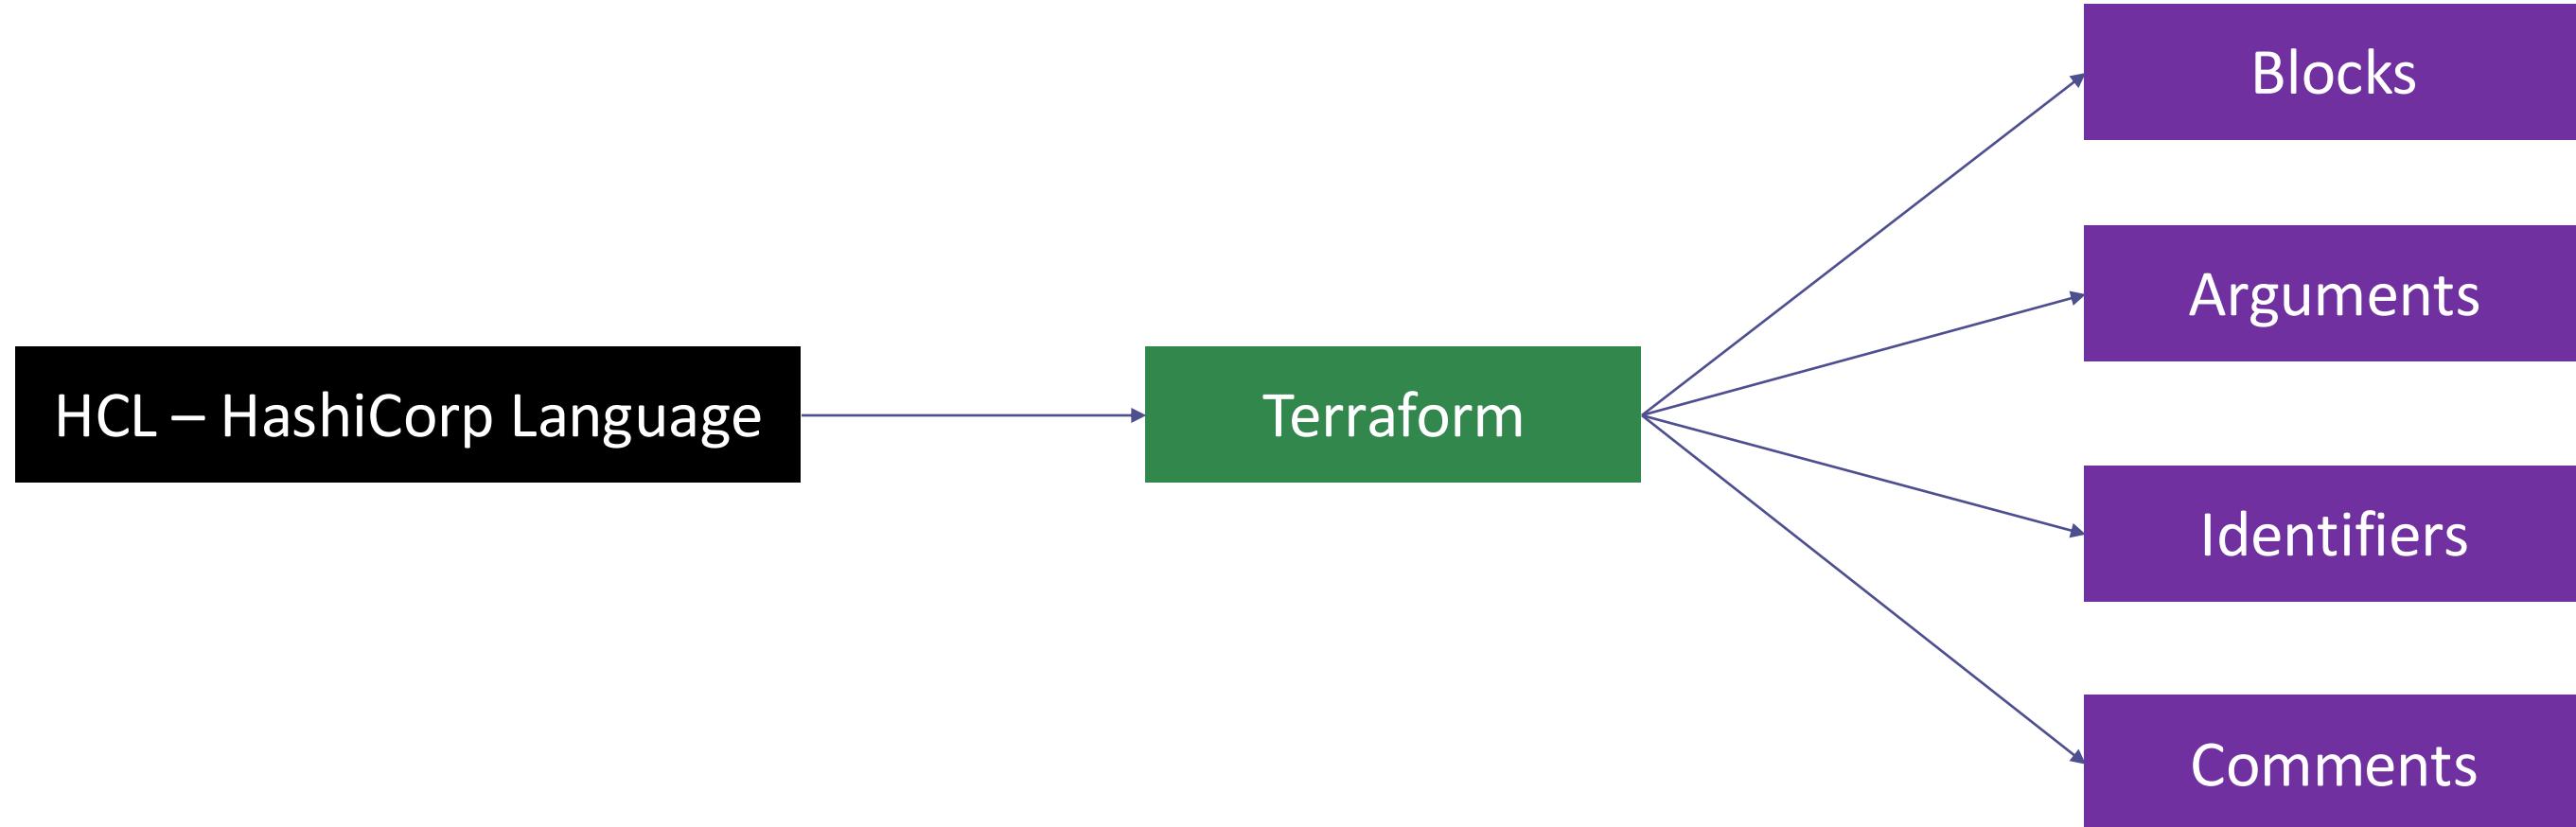

- Code in the Terraform language is stored in plain text files with the **.tf** file extension.
- There is also a JSON-based variant of the language that is named with the **.tf.json** file extension.
- We can call the files containing terraform code as **Terraform Configuration Files** or **Terraform Manifests**
- Terraform files should be saved in a directory (**Terraform Working Directory**)

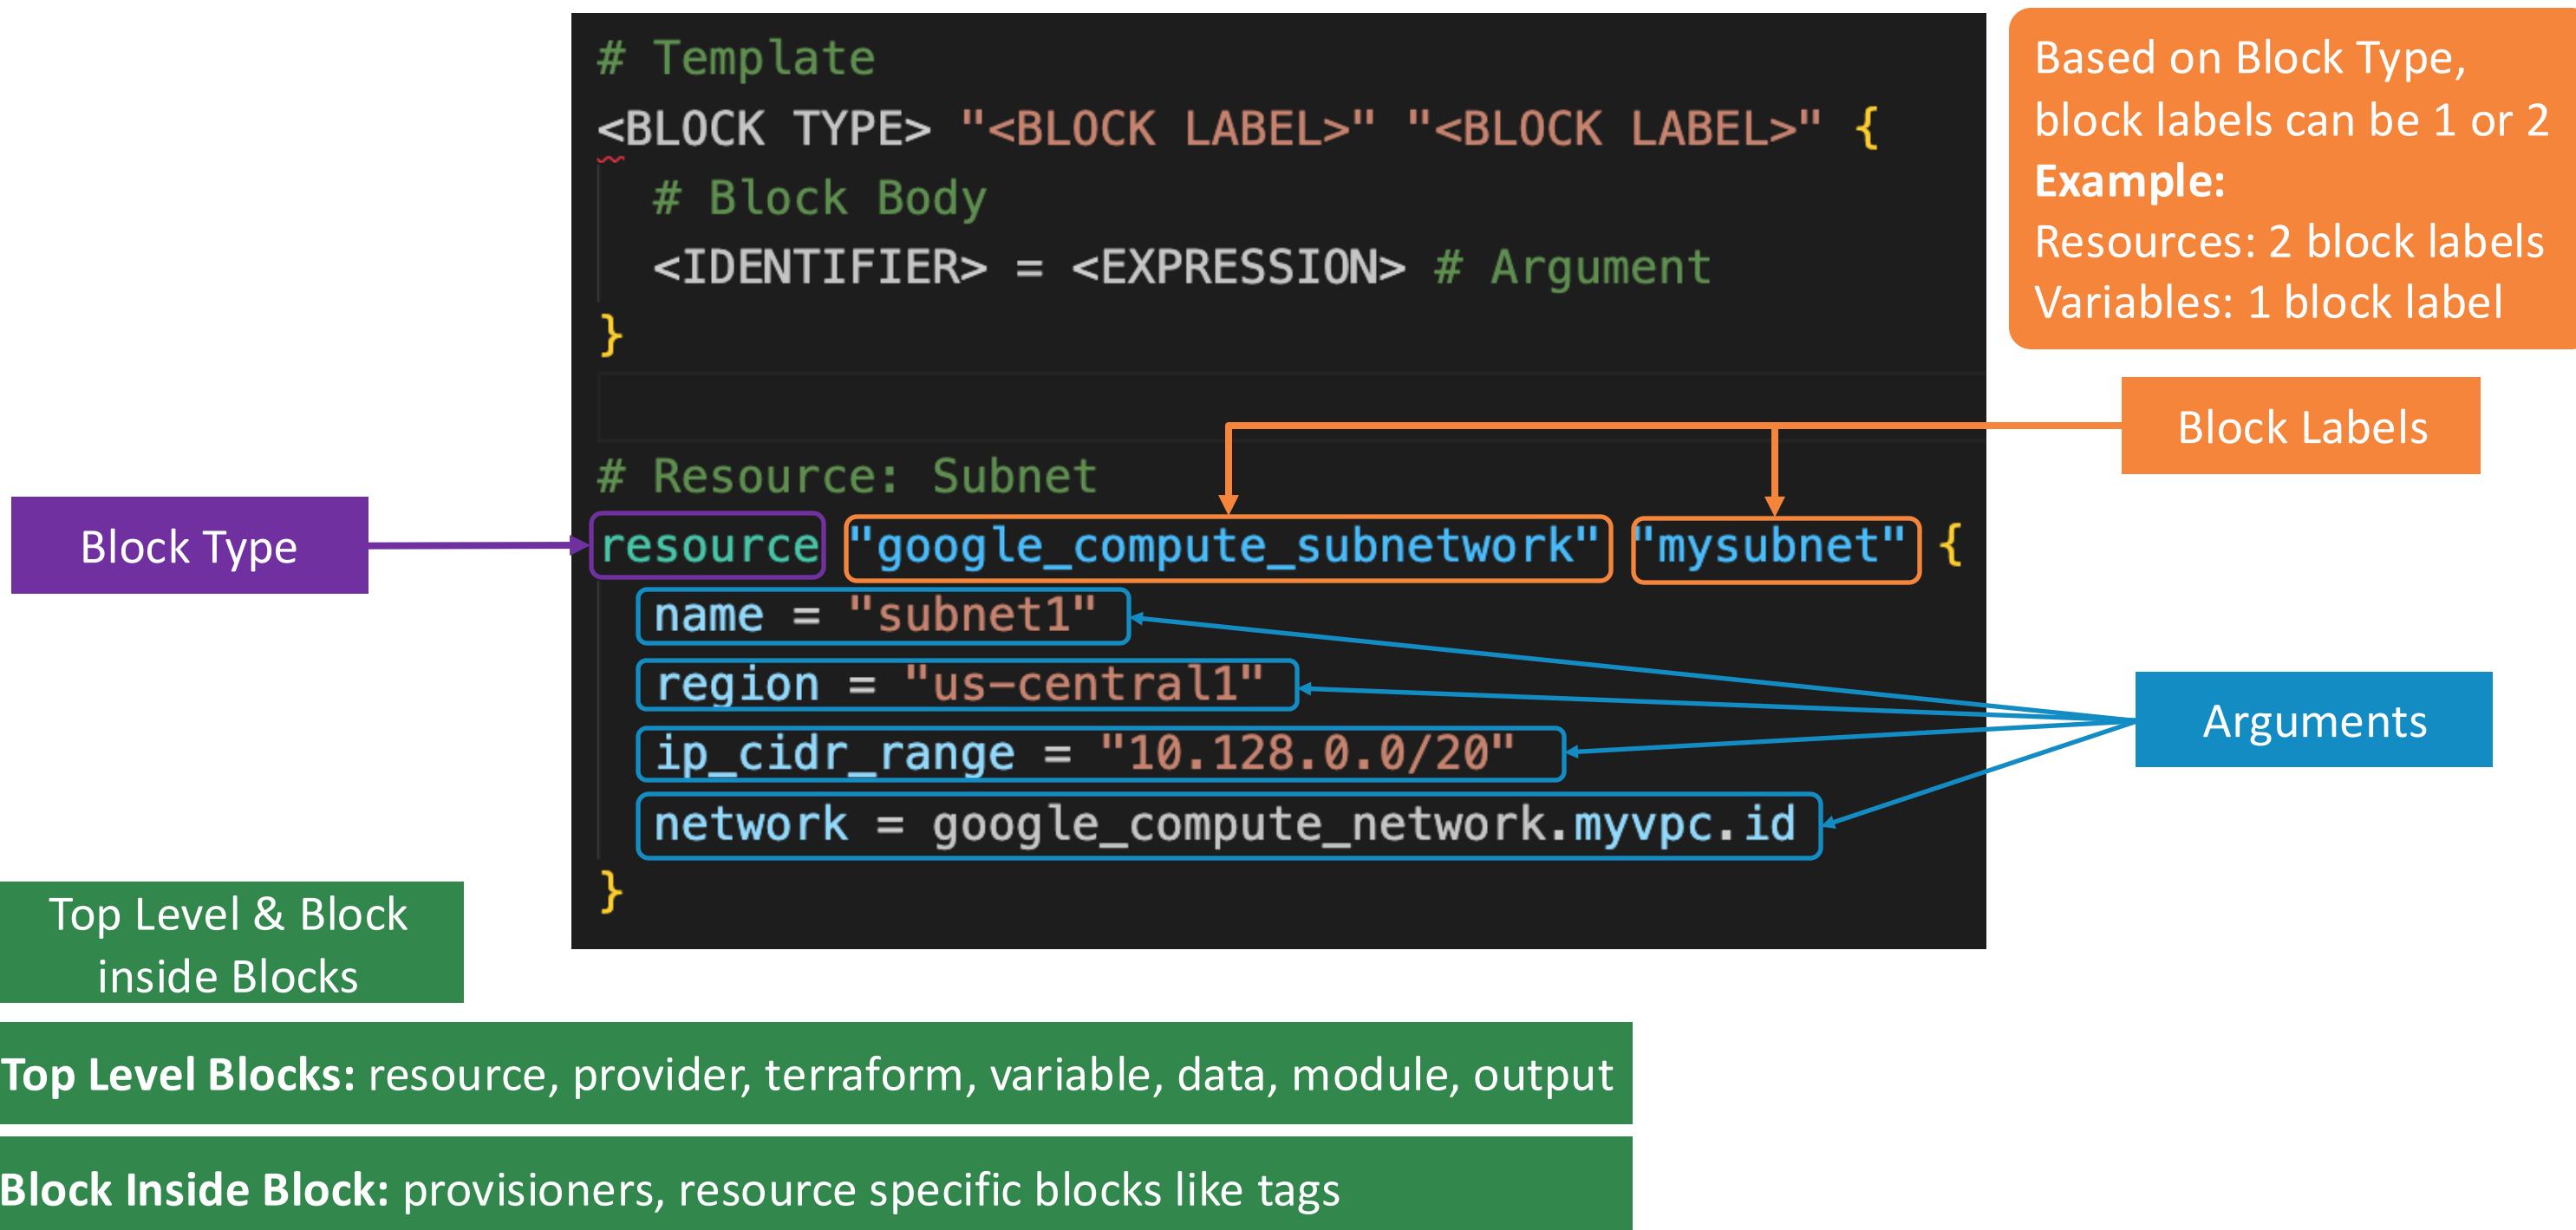

Terraform Working
Directory

Terraform Configuration Files
ending with **.tf** as extension

Terraform Language Basics - Configuration Syntax

Terraform Language Basics - Configuration Syntax

Terraform Language Basics - Configuration Syntax

```
# Template
<BLOCK TYPE> "<BLOCK LABEL>" "<BLOCK LABEL>" {
  # Block Body
  <IDENTIFIER> = <EXPRESSION> # Argument
}
```

```
# Resource: Subnet
resource "google_compute_subnetwork" "mysubnet" {
```

Argument
Name
[OR]
Identifier

name = "subnet1"
region = "us-central1"
ip_cidr_range = "10.128.0.0/20"
network = google_compute_network.myvpc.id

Argument
Value
[OR]
Expression

Terraform Language Basics - Configuration Syntax

Multi-line comment /* */

```
/*
# Template
<BLOCK TYPE> "<BLOCK LABEL>" "<BLOCK LABEL>" {
    # Block Body
    <IDENTIFIER> = <EXPRESSION> # Argument
}
*/
```

Single Line Comments with # or //

```
# Resource: Subnet
resource "google_compute_subnetwork" "mysubnet" {
    name          = "subnet1"
    region        = "us-central1"
    ip_cidr_range = "10.128.0.0/20"
    network       = google_compute_network.myvpc.id // GET VPC ID
}
```

Terraform language uses a **limited** number of **top-level block** types, which are **blocks** that can appear **outside** of any other **block** in a TF configuration file.

Terraform Top-Level Blocks

Most of **Terraform's features** are implemented as **top-level** blocks.

Terraform Block

Providers Block

Resources Block

Fundamental Blocks

Input Variables Block

Output Values Block

Local Values Block

Variable Blocks

Data Sources Block

Modules Block

Calling / Referencing Blocks

Import Block

Moved Block

Removed Block

Check Block

NEW BLOCKS – Added Recently

Demo

Terraform Fundamental Blocks

Terraform Basic Blocks

Terraform Block

Special block used to configure some **behaviors**

Specifying a **required Terraform Version**

Specifying **Provider Requirements**

Configuring a Terraform Backend (**Terraform State**)

Provider Block

HEART of Terraform

Terraform relies on providers to **interact** with Remote Systems

Declare providers for Terraform to **install** providers & use them

Provider configurations belong to **Root Module**

Resource Block

Each Resource Block describes one or more Infrastructure Objects

Resource Syntax:
How to declare Resources?

Resource Behavior: How Terraform handles resource declarations?

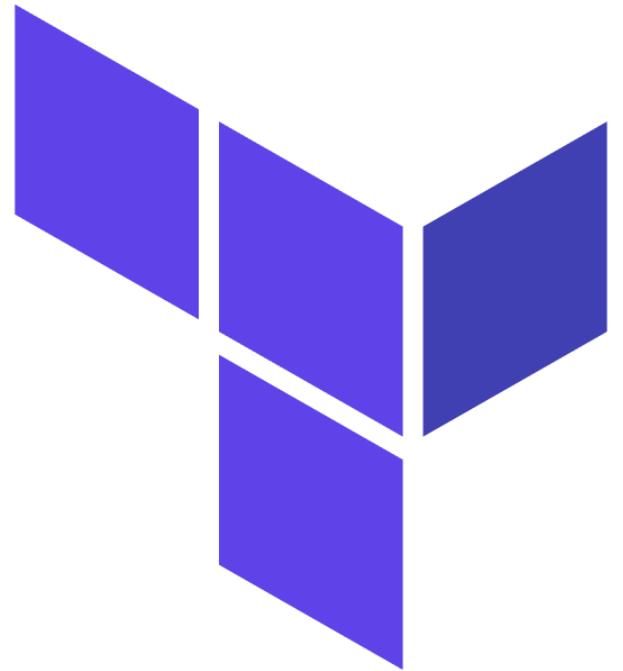

Provisioners: We can configure Resource post-creation actions

Demo

Terraform

Terraform Block

Terraform Block

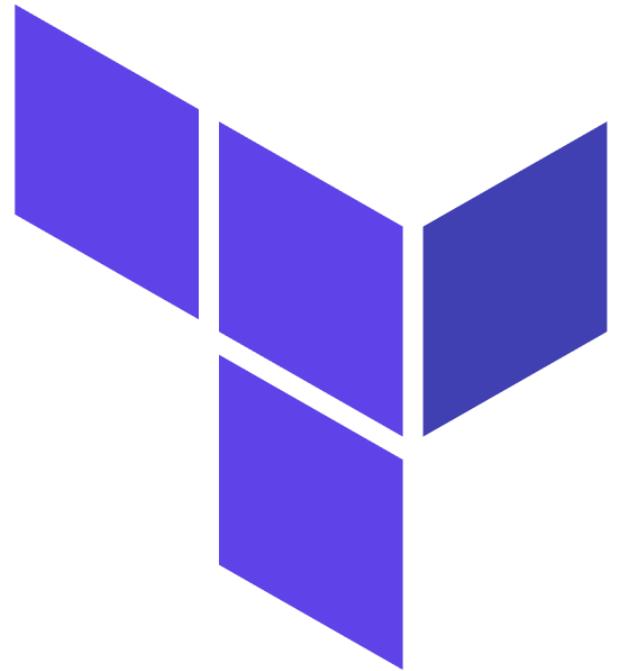

- This block can be called in 3 ways. All means the same.
 - Terraform Block
 - Terraform Settings Block
 - Terraform Configuration Block
- Each terraform block can contain a number of settings related to Terraform's behavior.
- Within a terraform block, **only constant values can be used**; arguments **may not refer** to named objects such as resources, input variables, etc, and **may not use any** of the Terraform language built-in functions.

```
# Terraform Settings Block
terraform {
    required_version = ">= 1.8"
    required_providers {
        google = {
            source  = "hashicorp/google"
            version = ">= 5.26.0"
        }
    }
    backend "gcs" {
        bucket  = "kalyanbucket201"
        prefix  = "terraform/state"
    }
}
```

Demo

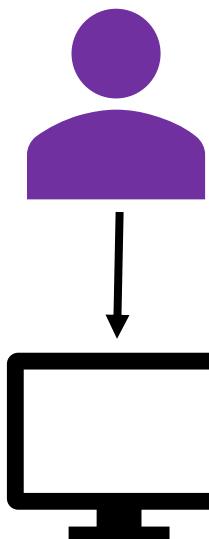

Terraform Providers

Terraform Providers

Terraform Admin

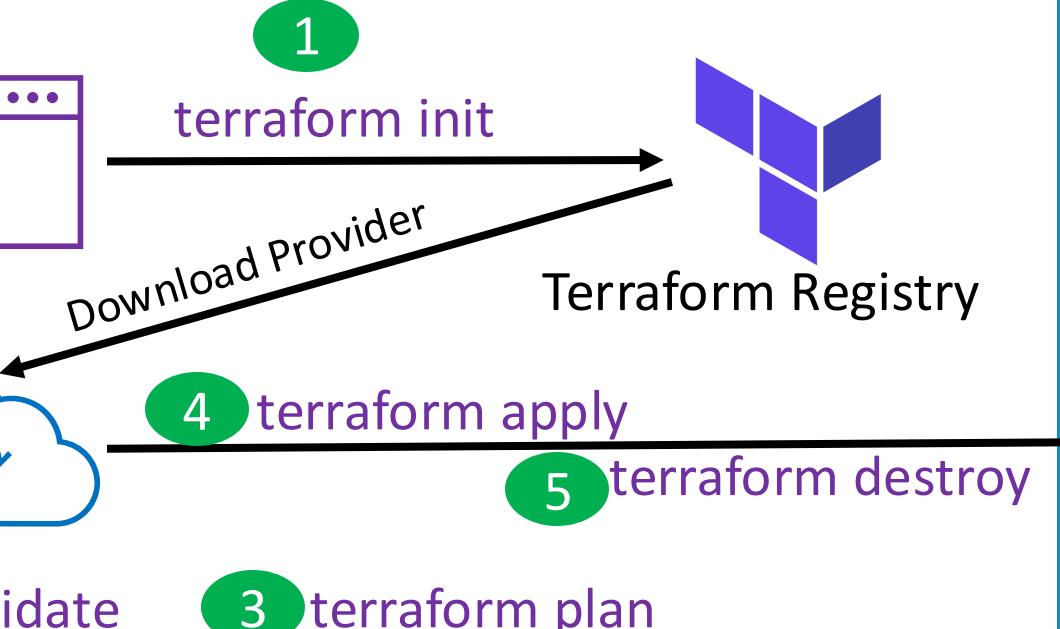

Local Desktop

Terraform CLI

Terraform GCP Provider

2 terraform validate

3 terraform plan

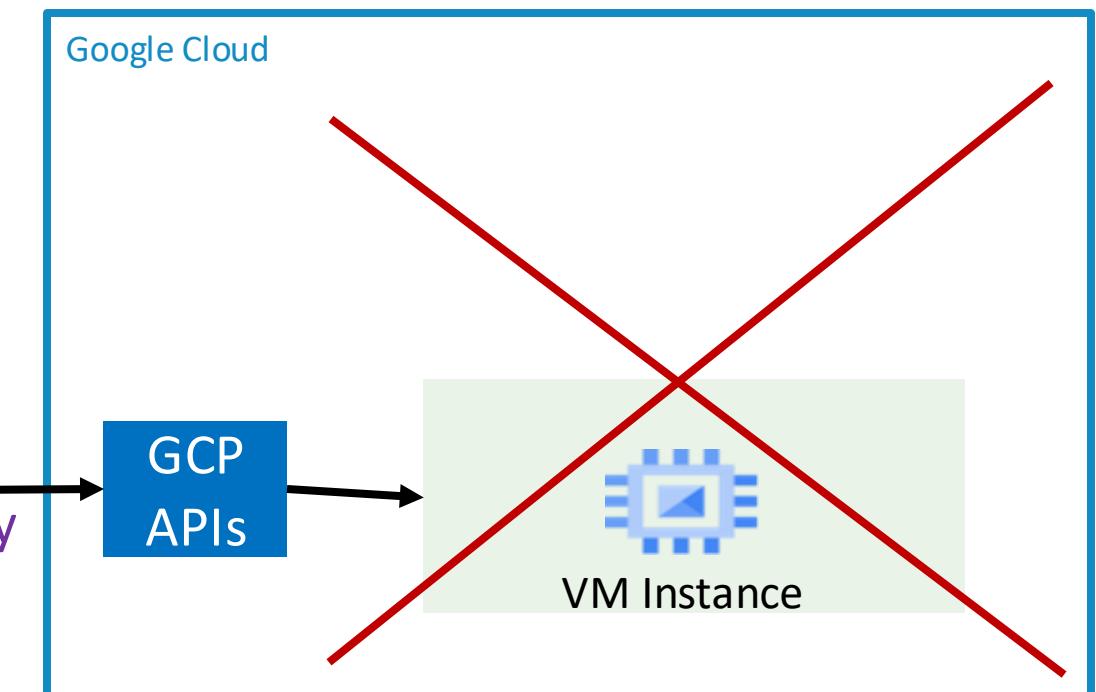

Providers are **HEART** of Terraform

Every **Resource Type** (example: VM Instance), is implemented by a Provider

Without Providers Terraform **cannot** manage any infrastructure.

Providers are distributed separately from Terraform and each provider has its own **release cycles** and **Version Numbers**

Terraform **Registry** is publicly available which contains many Terraform Providers for most **major** Infra Platforms

Provider Requirements

```
# Terraform Settings Block
terraform {
  required_version = ">= 1.8"
  required_providers {
    google = {
      source = "hashicorp/google"
      version = ">= 5.26.0"
    }
  }
}
```

Terraform Providers

Provider Configuration

```
# Terraform Provider Block
provider "google" {
  project = "gcplearn9"
  region = "us-central1"
}
```

Dependency Lock File

```

21  ]
22 }
23
```

Required Providers

```
# Terraform Settings Block
terraform {
  required_version = ">= 1.8"
  required_providers {
    google = {
      source = "hashicorp/google"
      version = ">= 5.26.0"
    }
  }
}

# Terraform Provider Block
provider "google" {
  project = "gcplearn9"
  region = "us-central1"
}
```

Local Names

Local Names are **Module specific** and should be **unique** per-module

Terraform configurations always refer to **local name** of provider **outside** required_provider block

Users of a provider can choose **any local name** for it (mygoogle, google1).

Recommended way of choosing local name is to use preferred local name of that provider (For Google Provider: hashicorp/google, **preferred local name** is google)

Source

It is the **primary location** where we can download the Terraform Provider

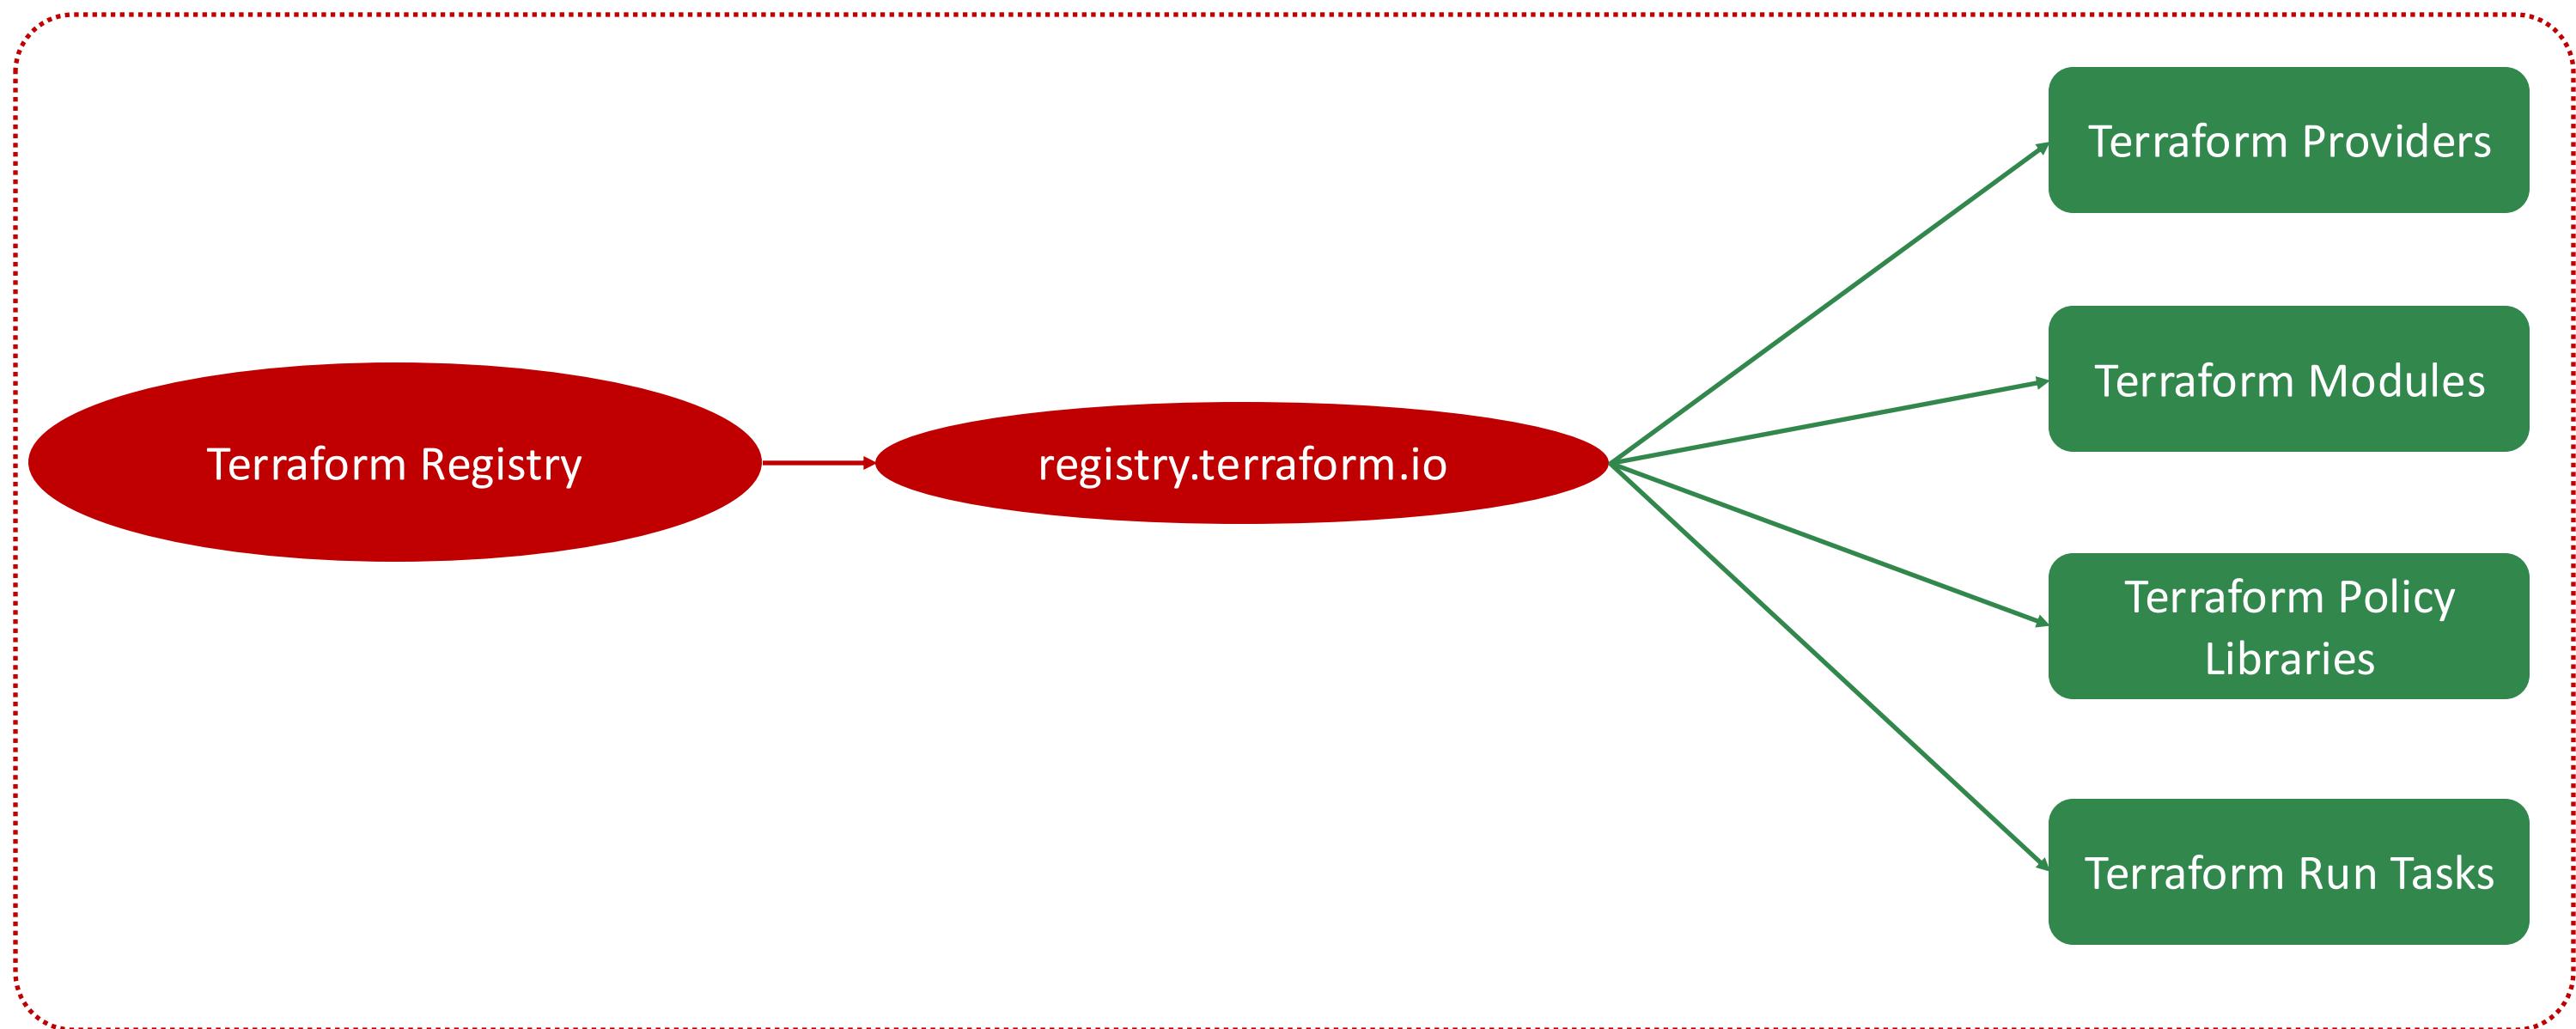

Source addresses consist of **three parts** delimited by **slashes (/)**

[<HOSTNAME>/]<NAMESPACE>/<TYPE>

registry.terraform.io/hashicorp/google

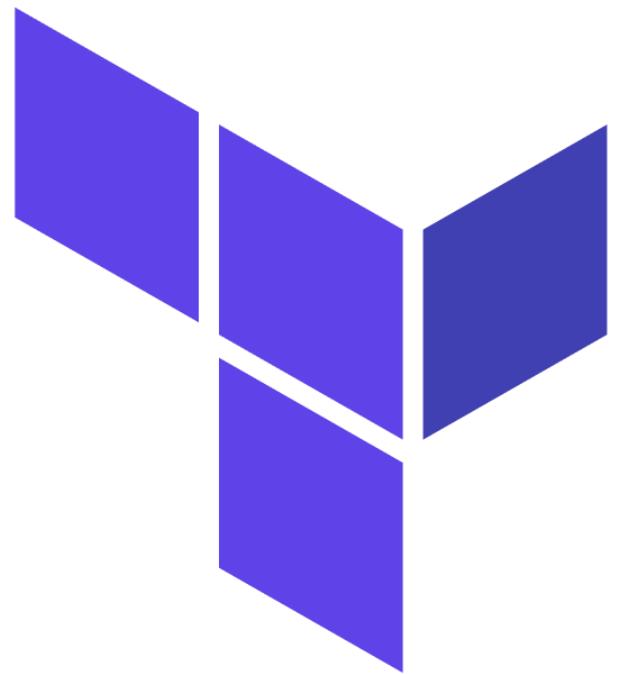

Registry Name is **optional** as default is going to be Terraform Public Registry

Terraform Registry

Demo

Terraform State

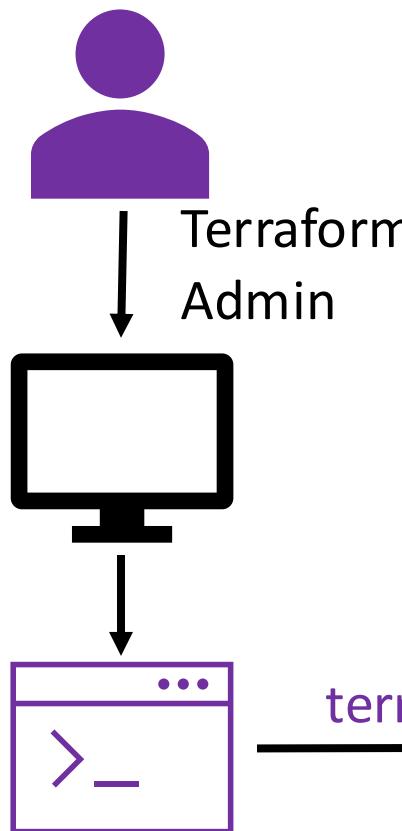

Terraform State

Local Desktop

Terraform CLI

Terraform AWS Provider

Terraform State
File : `terraform.tfstate`

- 2 `terraform validate`
- 3 `terraform plan`

Terraform must **store state** about your managed infrastructure and configuration (.tf files), keep track of metadata, and to **improve performance** for large infrastructures.

This state is stored by default in a local file named "**terraform.tfstate**", but it can also be stored **remotely**, which works better in a **team** environment.

1

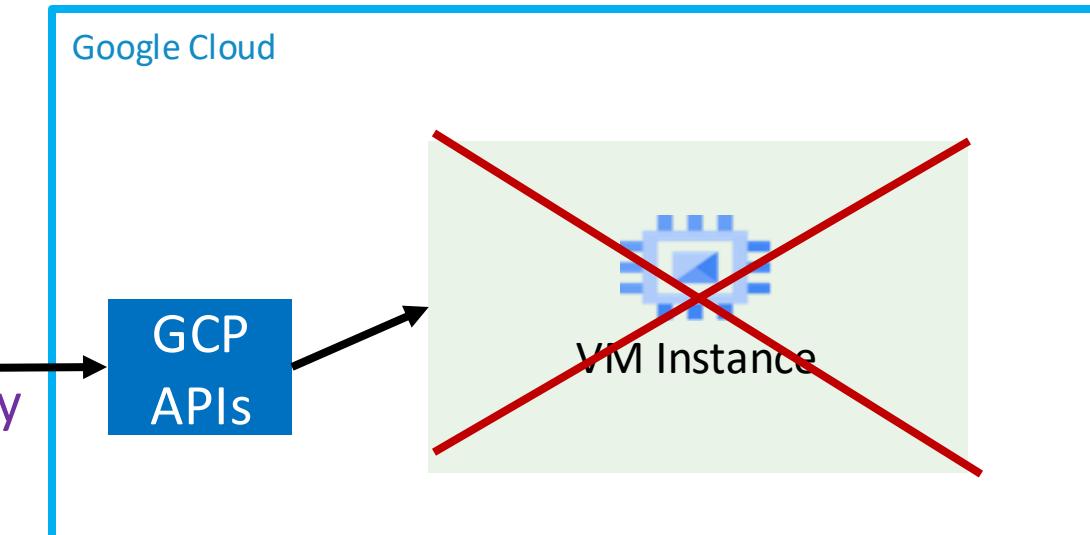

`terraform init`

Download Provider

Terraform Registry

4 `terraform apply`

5 `terraform destroy`

Demo-4

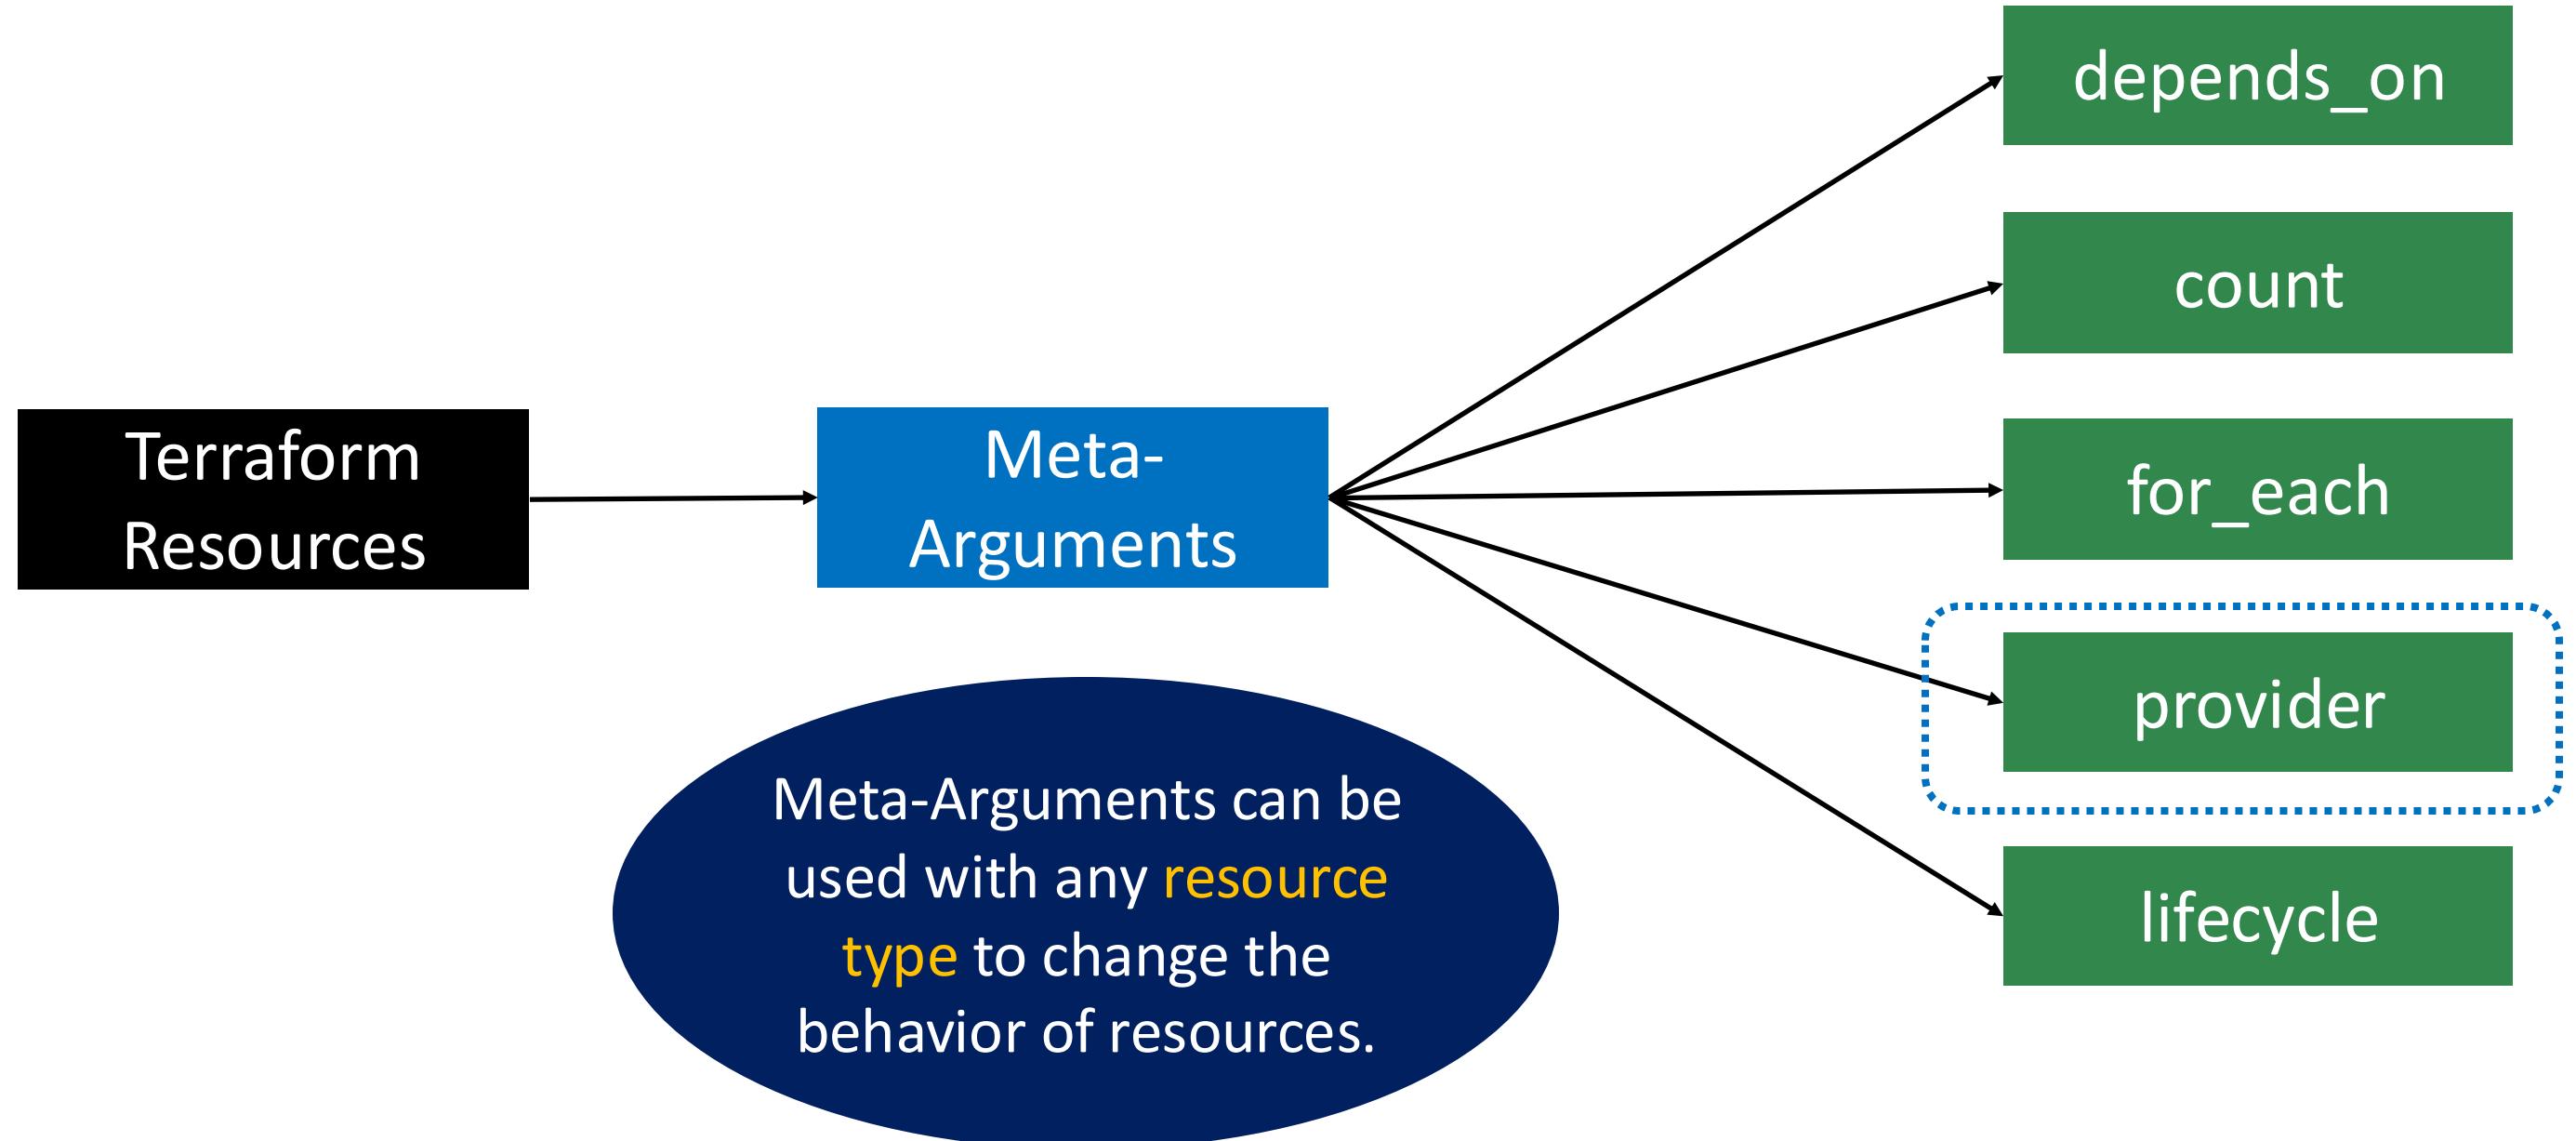

Terraform

Multiple Providers

Meta-Argument: provider

Resource Meta-Arguments

Terraform Multiple Providers

- We can define **multiple configurations** for the same provider (Ex: google) and select which one to use **on a per-resource or per-module basis**.
- The primary reason for this is to **support multiple regions for a cloud platform**, additionally for **multiple environments** (dev, prod) considering each environment has different provider configurations (**Example: different authentication credentials for dev and prod**)
- We can use the alternate provider in a resource, data or module by referencing it as **<PROVIDER NAME>.<ALIAS>**

```
# Terraform Provider-1: us-central1
provider "google" {
  project = "gcplearn9"
  region = "us-central1"
  alias = "us-central1"
}

# Terraform Provider-2: europe-west1
provider "google" {
  project = "gcplearn9"
  region = "europe-west1"
  alias = "europe-west1"
}
```

```
# Resource: Subnet1
resource "google_compute_subnetwork" "mysubnet1" {
  provider = google.us-central1 # Define provider to use
  name = "subnet1"
  ip_cidr_range = "10.128.0.0/20"
  network = google_compute_network.myvpc.id
}

# Resource: Subnet2
resource "google_compute_subnetwork" "mysubnet2" {
  provider = google.europe-west1 # Define provider to use
  name = "subnet2"
  ip_cidr_range = "10.132.0.0/20"
  network = google_compute_network.myvpc.id
}
```

Terraform Multiple Providers

- We can define **multiple configurations** for the same provider (Ex: google) and select which one to use **on a per-resource or per-module basis**.
- **Usage**
 - To support **multiple regions** for a cloud platform (we will practically implement this)
 - For supporting **multiple environments (dev, prod)** considering each environment has different provider configurations
 - **Example:** Different authentication credentials for **dev** and **prod** configured in their respective provider blocks
 - We can use the alternate provider in a resource, data or module by referencing it as <PROVIDER NAME>.<ALIAS>

```

# Terraform Provider-1: us-central1
provider "google" {
  project = "gcplearn9"
  region  = "us-central1"
  alias   = "us-central1"
}

# Terraform Provider-2: europe-west1
provider "google" {
  project = "gcplearn9"
  region  = "europe-west1"
  alias   = "europe-west1"
}

# Resource: Subnet1
resource "google_compute_subnetwork" "mysubnet1" {
  provider = google.us-central1 # Define provider to use
  name     = "subnet1"
  ip_cidr_range = "10.128.0.0/20"
  network  = google_compute_network.myvpc.id
}

# Resource: Subnet2
resource "google_compute_subnetwork" "mysubnet2" {
  provider = google.europe-west1 # Define provider to use
  name     = "subnet2"
  ip_cidr_range = "10.132.0.0/20"
  network  = google_compute_network.myvpc.id
}

```

Terraform Multiple Providers

Update multiple providers

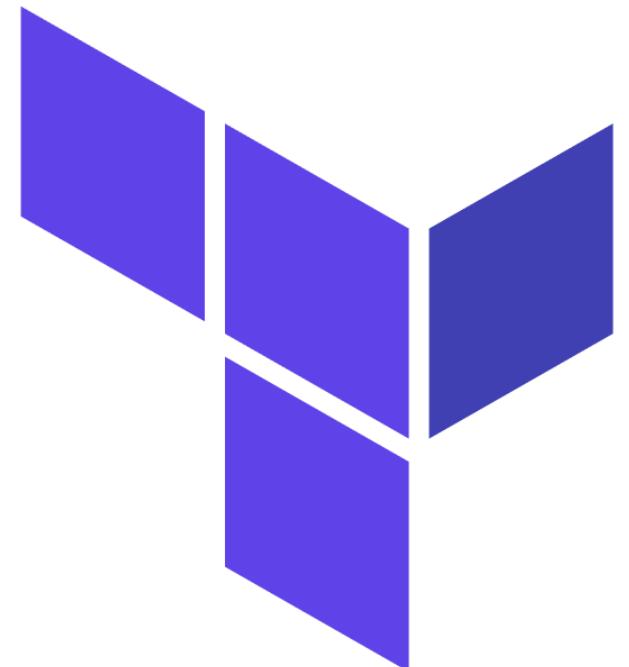

C2

Use provider alias in subnet Terraform resources

Demo-5

Terraform Input Variables Output Values

Demo: Terraform Concept: Input Variables and Output Values

Terraform Input Variables

- Input variables allow us to **customize** the Terraform Resources or modules without altering the source code.
- **Key Benefit:** Allows us to make the **code reusable** by just changing variables
- We have **multiple options** to declare variables
 - variables.tf (Default value)
 - terraform.tfvars
 - vm.auto.tfvars
 - vm.tfvars
 - Environment Variables
 - --var-file flag
 - --var flag

variables.tf

```
# GCP Compute Engine Machine Type
variable "machine_type" {
  description = "Compute Engine Machine Type"
  type        = string
  default     = "e2-small"
}
```

terraform.tfvars

```
terraform.tfvars ×
terraform-on-google-cloud > 05-Terraform-Variables-Output-Values >
  1 gcp_project      = "gcplearn9"
  2 gcp_region1     = "us-central1"
  3 machine_type    = "e2-micro"
```

Understand and define Terraform **Input Variables**

C1

Update **Provider** block with Terraform input variables

C3

Update **subnet region** with input variable

C5

Update **VM Instance machine type** using input variable

TF
VARS

Play with **terraform.tfvars**, **vm.auto.tfvars** and **vm.tfvars**

```
# Terraform Output Values
## ATTRIBUTES
output "vm_instanceid" {
  description = "VM Instance ID"
  value = google_compute_instance.myapp1.instance_id
}

output "vm_selflink" {
  description = "VM Instance Self link"
  value = google_compute_instance.myapp1.self_link
}
```

```
## ARGUMENTS
output "vm_name" {
  description = "VM Name"
  value = google_compute_instance.myapp1.name
}

output "vm_machine_type" {
  description = "VM Machine Type"
  value = google_compute_instance.myapp1.machine_type
}
```

Terraform Output Values

- Output values are like **return values** in programming languages.
- Output values provide about your infrastructure available on the **command line**
- With output values we can **expose information** for other Terraform configurations to use

Output Values

Outputs:

```
vm_external_ip = "34.45.238.213"
vm_id = "projects/gcplearn9/zones/us-central1-a/instances/myapp1"
vm_instanceid = "3515727697506246169"
vm_machine_type = "e2-micro"
vm_name = "myapp1"
vm_selflink = "https://www.googleapis.com/compute/v1/projects/gcplearn9/zones/u
s-central1-a/instances/myapp1"
```

Demo-6

Terraform Meta-Argument count

Demo: Terraform Concept: Meta-argument count

Terraform Meta-Argument: count

- By default, resource block creates a **single instance** of a resource
 - **For example:** 1 VM Instance
- With the meta-argument **count** we can create **specified number of similar instances** of a resource
 - **For example:** **count = 2** (will create **2 VM instances** from the same defined resource block)
 - **count.index:** The distinct index number (**starting with 0**) corresponding to this instance.

Resource Meta-Argument: count

```
# Resource Block: Create a Compute Engine instance
resource "google_compute_instance" "myapp1" {
    # Meta-Argument: count
    count = 2
    name      = "myapp1-vm-${count.index}"
    machine_type = var.machine_type
    zone       = "us-central1-a"
```

Terraform Meta-argument: count

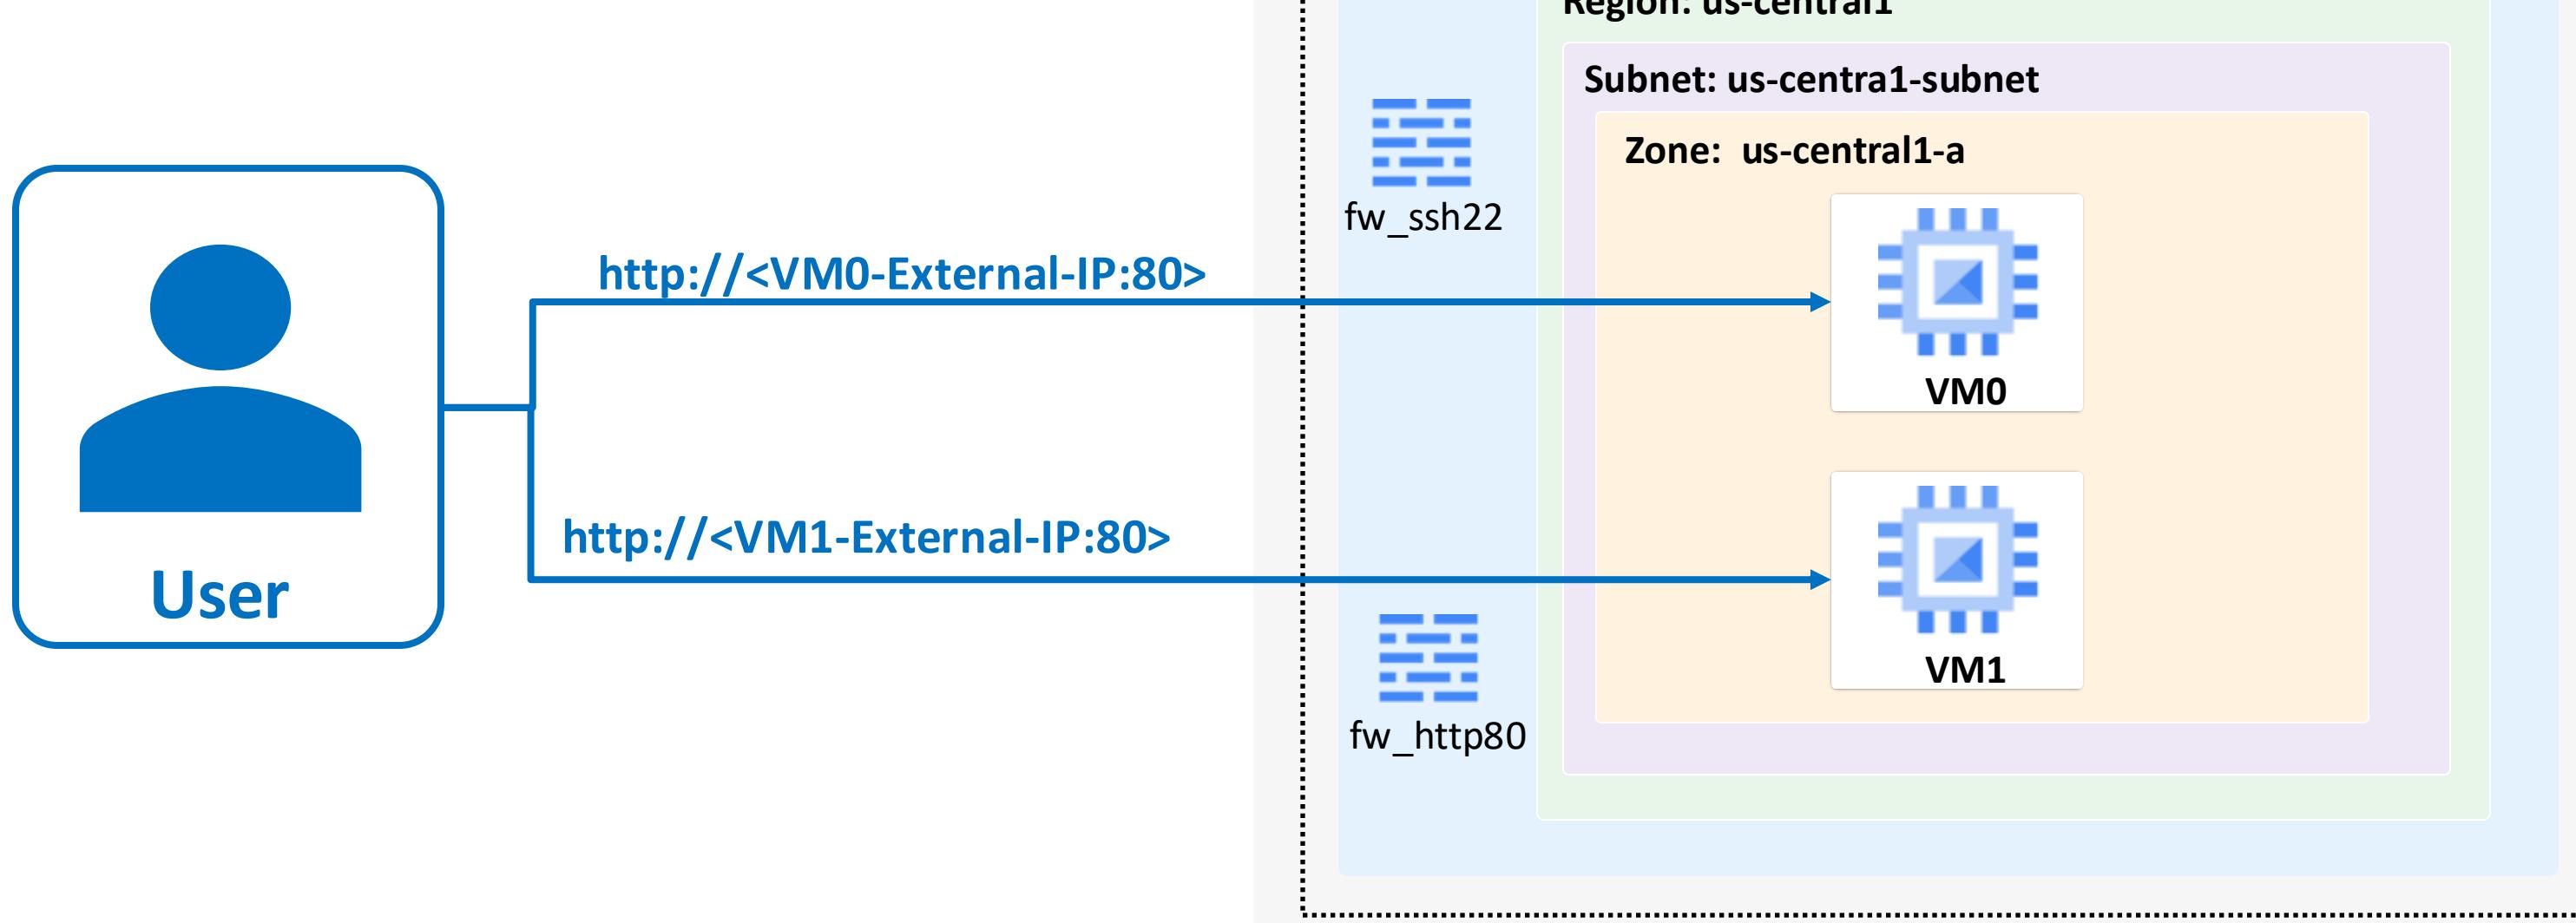

Customer Project: gcplearn9

VPC: vpc1

Automated by Terraform

Terraform: For expression

- **For Expression:** Enables efficient management of multiple resources by [looping](#) through lists, maps, or sets

- **Examples:**

- For loop with [list](#)
- For loop with [map](#)
- For loop with [map advanced](#)
- [Legacy splat operator](#)
- [Latest generalized splat operator](#)

For expression

```
# Output - For Loop with List
output "for_output_list" {
  description = "For Loop with List"
  value = [for instance in google_compute_instance.myapp1: instance.name]
}

# Output - For Loop with Map
output "for_output_map1" {
  description = "For Loop with Map"
  value = {for instance in google_compute_instance.myapp1: instance.name => instance.instance_id}
}

# Output - For Loop with Map Advanced
output "for_output_map2" {
  description = "For Loop with Map - Advanced"
  value = {for c, instance in google_compute_instance.myapp1: c => instance.name}
}
```

```
# Output Legacy Splat Operator (Legacy) - Returns the List
output "legacy_splat_instance" {
  description = "Legacy Splat Operator"
  value = google_compute_instance.myapp1.*.name
}

# Output Latest Generalized Splat Operator - Returns the List
output "latest_splat_instance" {
  description = "Generalized latest Splat Operator"
  value = google_compute_instance.myapp1[*].name
}
```

Demo-7

Terraform Data sources

Demo: Terraform Concept: Datasources

Terraform Data sources

- **Data sources:** allow Terraform to **use information defined outside** of Terraform
- A data source is accessed via a special kind of resource known as a **data resource**, declared using a **data block**:
- **Use case:**
 - **Step-01:** Get the **available compute zones** in that respective region using **google_compute_zone** datasource
 - **Step-02:** Create **two VM Instances** in two available compute zones using the **Meta-argument count**

Terraform Data source

```
# Terraform Datasources
/* Datasource: Get a list of Google
Compute zones that are UP in a region */
data "google_compute_zones" "available" {
  status = "UP"
}

# Output value
output "compute_zones" {
  description = "List of compute zones"
  value = data.google_compute_zones.available.names
}
```

Define a data source to get a list of all available zones in that region

Update VM Instance with zone value updated from Terraform data source

Demo-8

Terraform Meta-Argument `for_each`

Demo: Terraform Concept: Meta-Argument `for_each`

Terraform Meta-Argument: `for_each`

- By default, resource block creates a **single instance** of a resource
 - **For example:** 1 VM Instance
- The **`for_each`** meta-argument accepts a **map or a set of strings** and **creates an instance** for each **item** in that **map or set**
 - **For example:** Creates 1 VM instance for each compute zone
- **Each instance has a**
 - **distinct** infrastructure object associated with it
 - **each** is **separately** created, updated, or destroyed when the configuration is applied

Resource Meta-Argument: `for_each`

```
# Resource Block: Create a Compute Engine instance
resource "google_compute_instance" "myapp1" {
    # Meta-Argument: for_each
    for_each = toset(data.google_compute_zones.available.names)
    name      = "myapp1-vm-${each.key}"
    machine_type = var.machine_type
    zone      = each.key # You can also use each.value because for list
    tags       = [tolist(google_compute_firewall.fw_ssh.target_tags)[0],
```

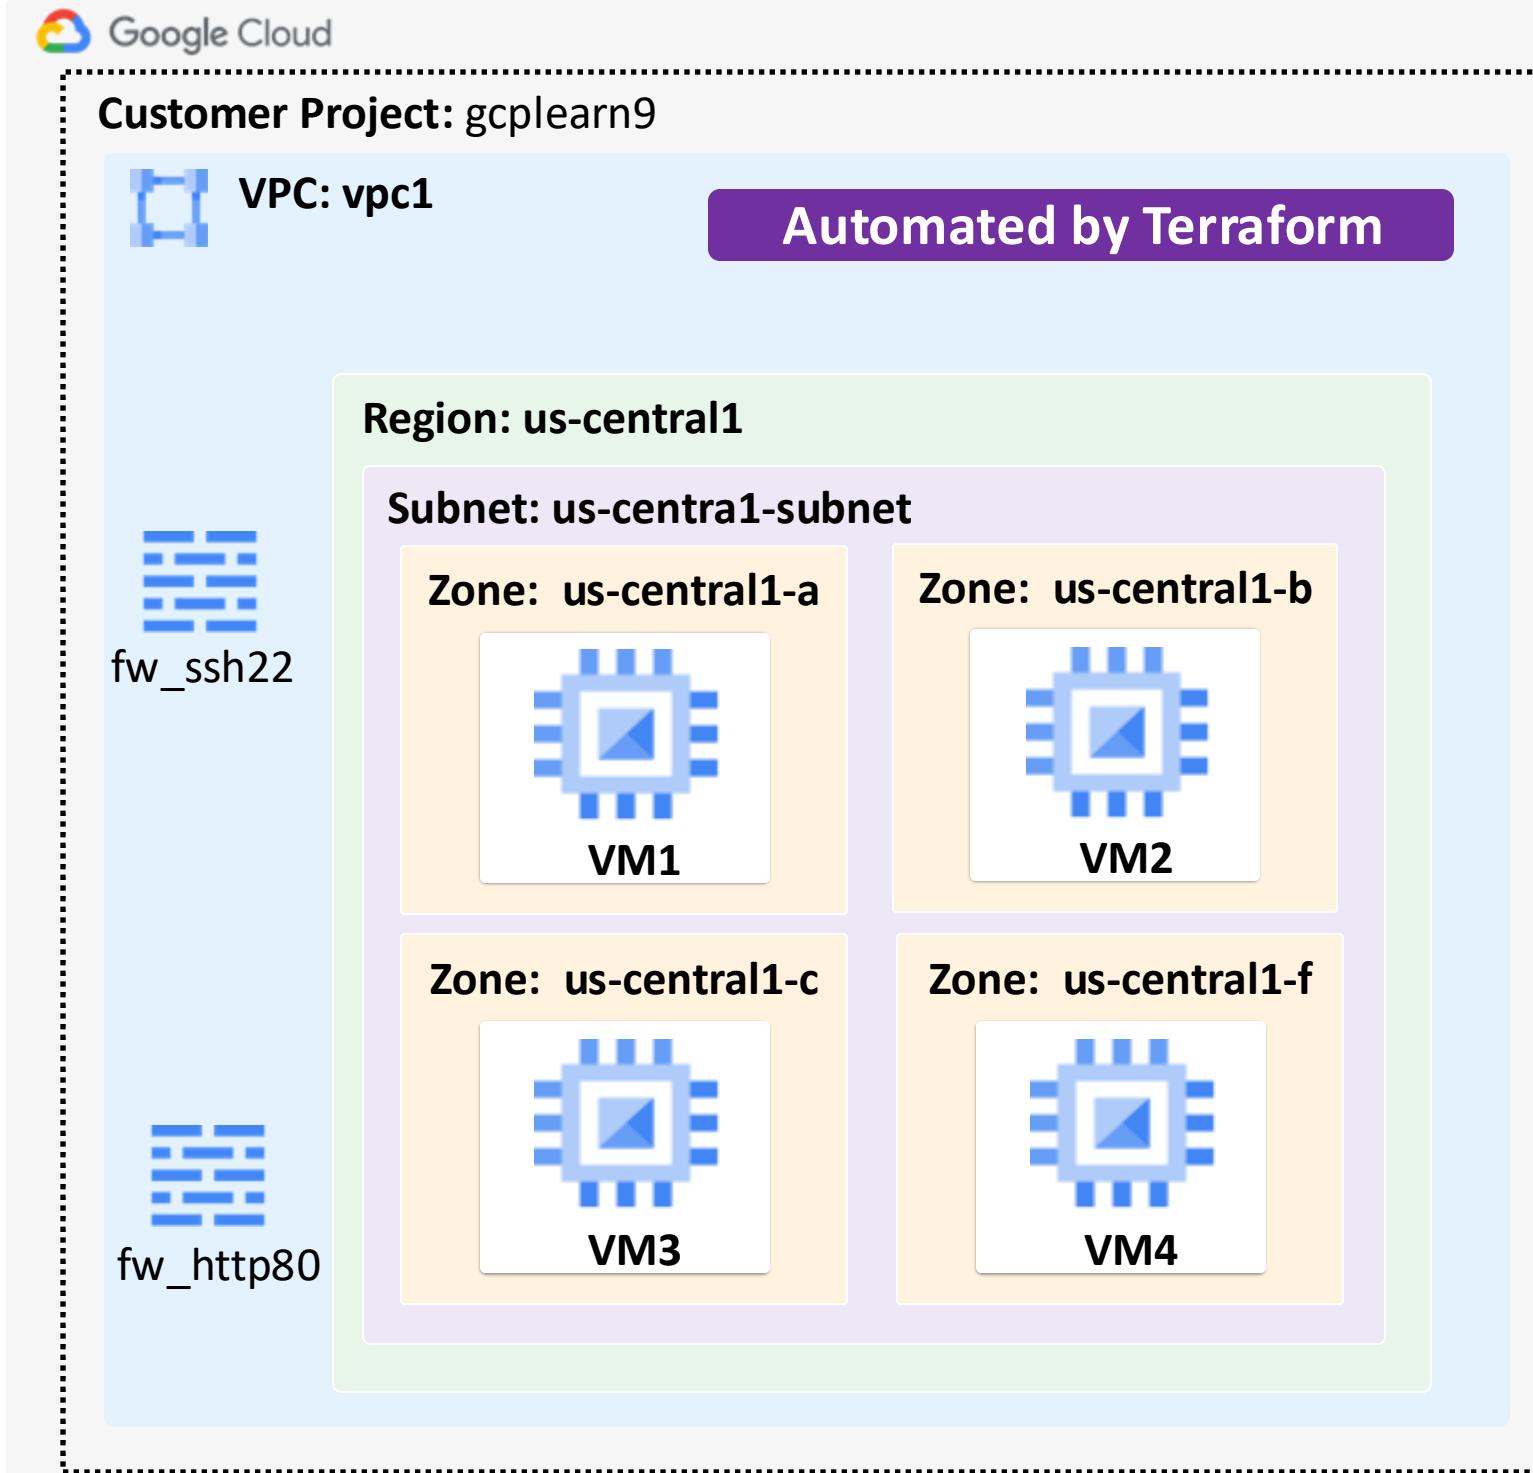

- **`each.key`:** The **map key (or set member)** corresponding to this instance.
- **`each.value`:** The **map value** corresponding to this instance (If a **set** was provided, **`each.key == each.value`**)

Terraform Meta-argument: for_each

Demo-1: for_each with Set values

Creates VM instance
for each available
compute zone in a
region

```
# Resource Block: Create a Compute Engine instance
resource "google_compute_instance" "myapp1" {
  # Meta-Argument: for_each
  for_each = toset(data.google_compute_zones.available.names)
  name      = "myapp1-vm-${each.key}"
  machine_type = var.machine_type
  zone       = each.key # You can also use each.value because
```

C6-01

VM Instance with **for_each** Meta-argument with
Map Values

Demo-9

Terraform Local Values

GCP Instance Templates

Demo: Custom VPC + Instance Template + VM Instance

Terraform Local Values

- **Local Values:** Assigns a **name** to an **expression**, so you can use the **name multiple times** within a module instead of **repeating** the expression
- Local values are like a function's **temporary local variables**
- **Usage:**
 - `local.name`
 - `local.owners`
- **Important Note:** Overusing local values can make the configuration **hard to read for future maintainers** by hiding the actual values used (use it wisely based on need)

Local Values

```
# Define Local Values in Terraform
locals {
    owners = var.business_division
    environment = var.environment
    name = "${var.business_division}-${var.environment}"
    #name = "${local.owners}-${local.environment}"
    common_tags = {
        owners = local.owners
        environment = local.environment
    }
}
```

Using Local values in Resources

```
# Resource: VPC
resource "google_compute_network" "myvpc" {
    name = "${local.name}-vpc"
    auto_create_subnetworks = false
}

# Resource: Subnet
resource "google_compute_subnetwork" "mysubnet" {
    name = "${var.gcp_region1}-subnet"
    region = var.gcp_region1
    ip_cidr_range = "10.128.0.0/20"
    network = google_compute_network.myvpc.id
}
```

GCP

Regional Application Load Balancer

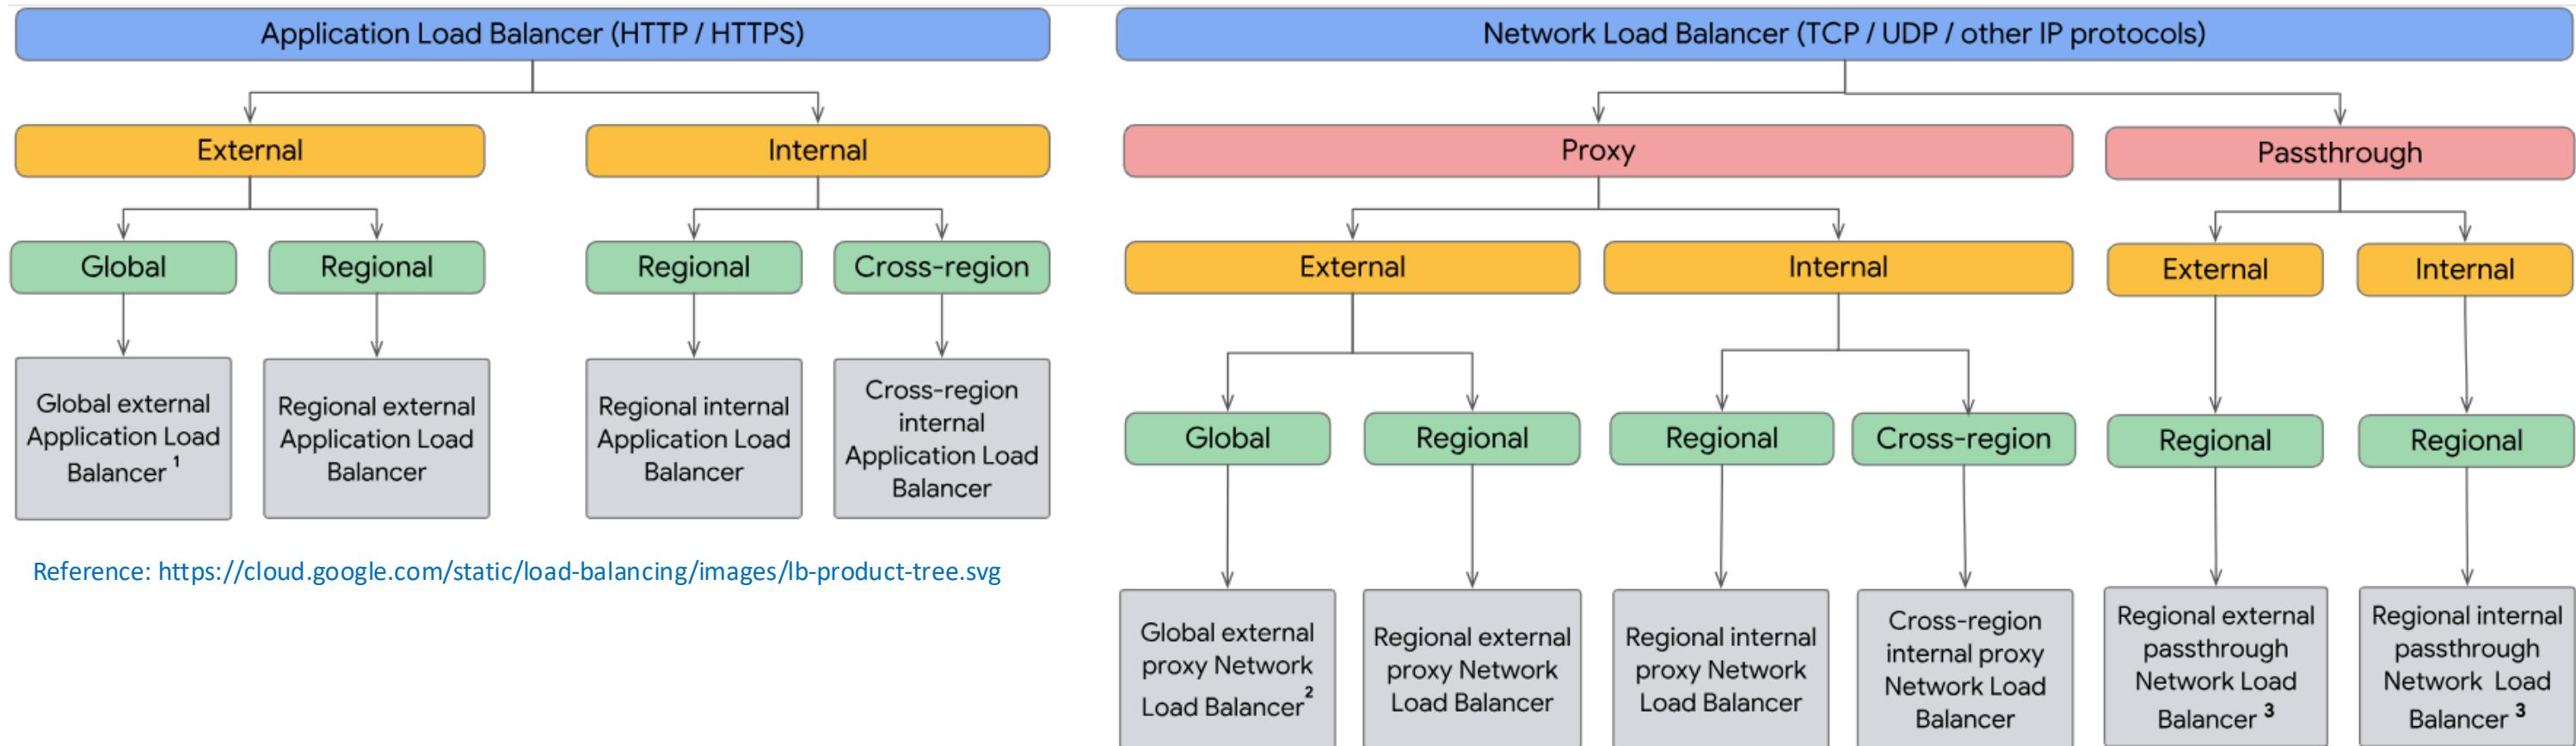

Demo: Custom VPC + Regional MIG Public IP +
Regional Application Load Balancer HTTP

GCP Cloud Load Balancing

- **Cloud Load Balancing:** Distributes user traffic across **multiple instances** of your applications
- Primarily used for providing **HIGH AVAILABILITY** for your applications
- Fully **distributed** managed service
 - **Global:** load balance **across regions**
 - **Regional:** load balancer **across zones** in a region
- **Layer7 Load Balancer**
 - Application load balancer
 - **HTTP or HTTPS**
- **Layer4 Load Balancer**
 - Network Load Balancers - **Proxy**
 - **TCP (TCP Proxy)**
 - **TCP with optional SSL offload (SSL Proxy)**
 - Network Load Balancers - **Pass-through**
 - **TCP, UDP, ICMP, ICMPv6, SCTP, ESP, AH, and GRE**

Google Cloud Load Balancing - Types

- We can create approximately **10 types** of Load Balancers
- On a very high-level, these are **categorized** as
 - Application Load Balancers
 - Network Load Balancers - **Proxy**
 - Network Load Balancers - **Pass-through**

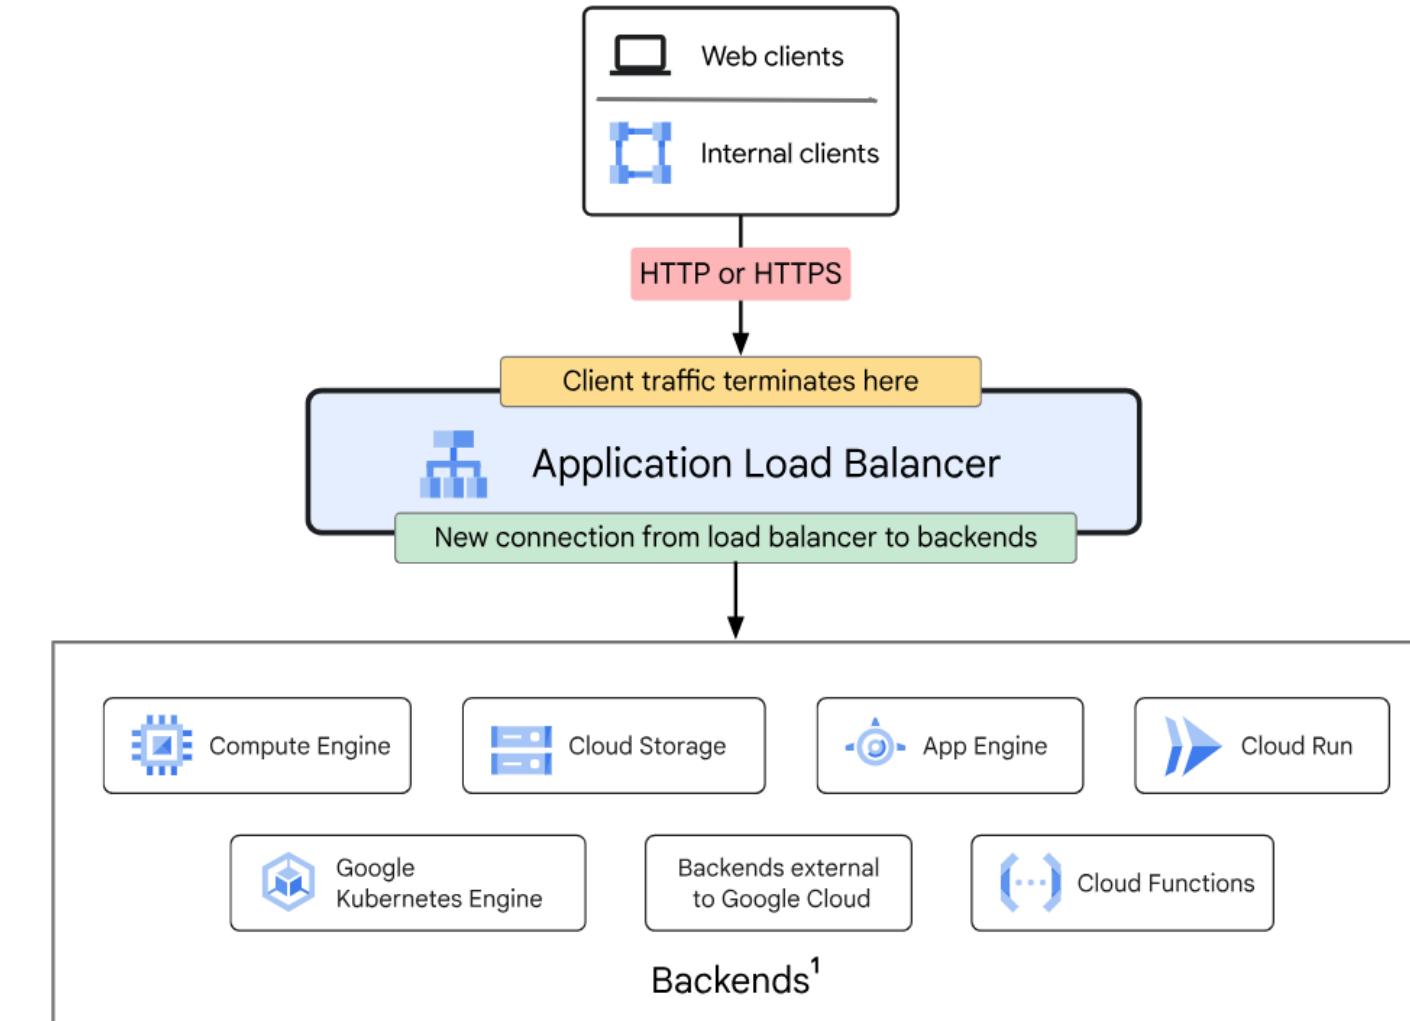

Google Cloud Load Balancing - Terminology

- **Backend**

- Google Cloud services that **receive traffic** from Load Balancer
 - Instance Groups
 - Cloud Storage
 - App Engine
 - Cloud Run
 - GKE
 - Cloud Functions
 - Backends external to Google Cloud

- **Frontend**

- Define **Load Balancer IP address, port, protocol (HTTP, HTTPS, TCP, UDP, SSL etc)**
- We will use this IP address to **access** the load balancer

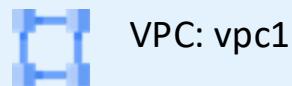

Reference: <https://cloud.google.com/static/load-balancing/images/application-load-balancer.svg>

Automated by Terraform

Google Cloud Load Balancing - Terminology

- **Proxy-Only Subnet**

- Uses **Envoy proxies** which **manage traffic routing and security**
- Provides **dedicated IP Address pool**
- **Routing:** These proxies **terminate connections from clients** and handle traffic routing based on factors like **URL Maps**
 - HTTP Path routing
 - Host header routing
 - Custom Header routing and many more
- **SSL:** Proxy layer can perform **advanced security functions** like
 - SSL Termination
- **Scalability:** Can be **automatically scaled** by GCP to meet traffic demands

Google Cloud Load Balancing - Terminology

- **Forwarding Rule:**

- Routes incoming traffic based on pre-defined criteria like IP address, port, and protocol.
- It directs traffic to a specific load balancing configuration.

- **Benefits:**

- Provides a single, easy-to-manage IP address for your application in DNS records.

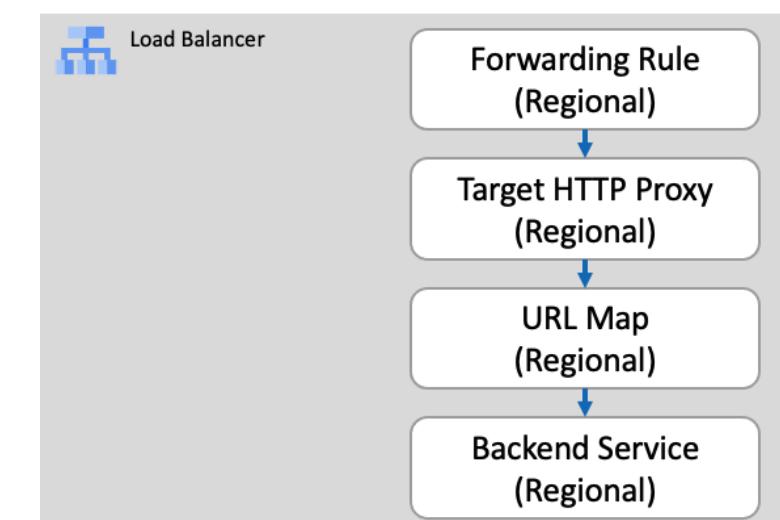

- **Target HTTP(S) Proxy:**

- Terminates client connections and acts as an intermediary between clients and backend services.
- It routes traffic based on forwarding rule configuration and URL map rules.

- **Benefits:**

- Can perform security functions like SSL termination (especially with Envoy proxies in regional external ALBs).

Subnet: us-central1-subnet-proxyonly
Proxy-Only Subnet (Regional)

Google Cloud Load Balancing - Terminology

- **URL Map:**

- Based on **pre-defined rules (url path, host header, custom header)** it determines the most **suitable backend service** to handle the request.

- **Benefits:**

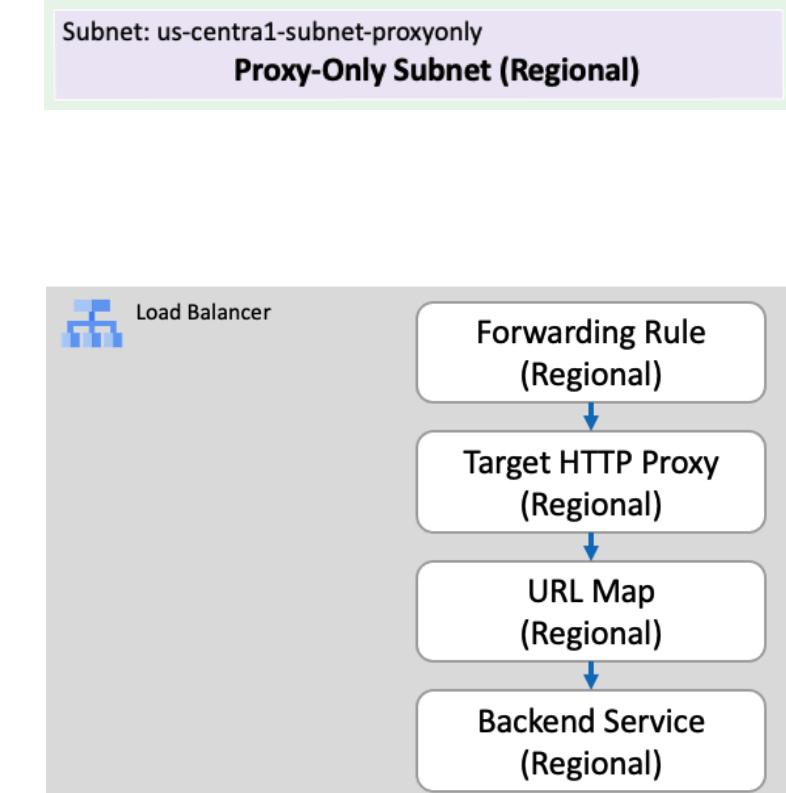

- Enables **intelligent traffic routing** based on specific **URL patterns**.
 - Path based Routing
 - Domain based Routing
 - Custom Header Routing

- **Backend Service:**

- Represents a **group of backend instances (VMs, containers)** that **handle incoming requests** routed by the load balancer.
- It distributes traffic across **healthy instances** based on the chosen load balancing algorithm.

- **Benefits:**

- Provides **high availability and scalability** for your application by ensuring requests reach healthy instances.
- Simplifies backend management by **hiding individual instances from the load balancer configuration** (you manage the backend service, not individual VMs).

Google Cloud Load Balancing - Terminology

- **Routing Rules (Application LBs)**

- **Path based Routing**

- App1: stacksimplify.com/app1
 - App2: stacksimplify.com/app2

- **Host based Routing**

- App1: app1.stacksimplify.com
 - App2: app2.stacksimplify.com

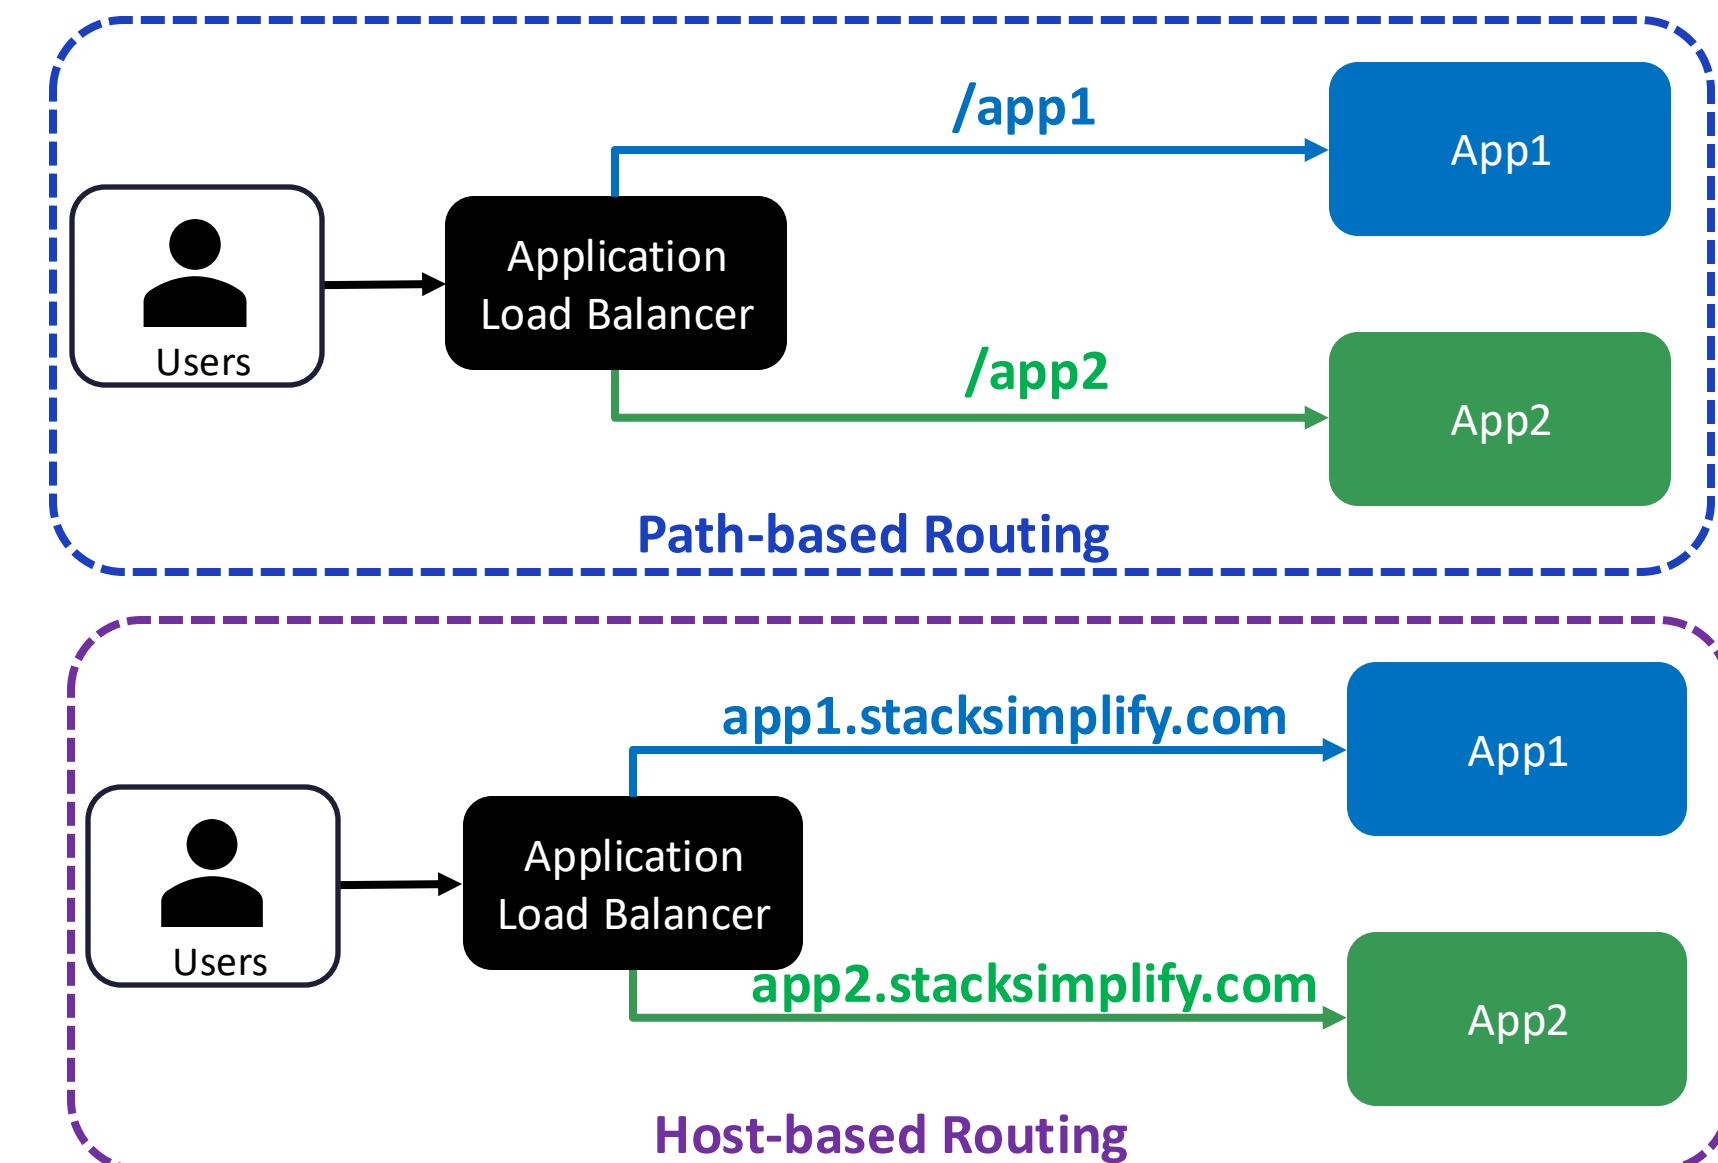

- **Rewrite the Requested URL**

- **Host Rewrite:** app1.stacksimplify.com to app1.terraformguru.com
 - **Path Rewrite:** stacksimplify.com/app1 to stacksimplify.com/app1new

- **Add and remove** request and response headers

- Configure a **URL redirect**

- Many many more things we can do

Regional Application Load Balancer HTTPS + Self-signed SSL**

GCP Load Balancer Self-signed SSL

- What are we going to implement?
- Create a HTTPS load balancer using self-signed SSL certificates with GCP certificate manager
- Implement HTTP to HTTPS redirect

What are we going to learn?

Demo: Custom VPC + Regional MIG Private IP +

No Changes from C1 to C6-05, C8

Create self signed SSL **private key and certificate**

Create **self-signed SSL certificate object using certificate manager**

Comment **HTTP proxy**, create **HTTPS proxy**, Update regional forwarding rule with **port 443**

Implement **HTTP to HTTPS redirect with URL Map, HTTP Proxy, Forwarding rule**

Update **HTTPS proxy output**

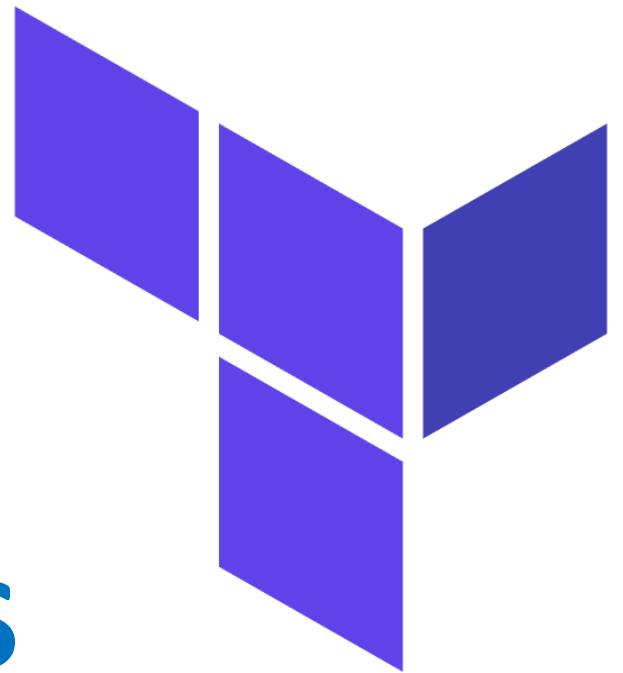

Demo-15

Terraform

GCP Load Balancer

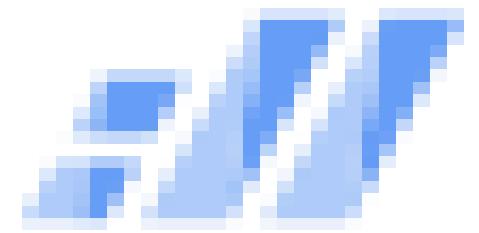

Cloud Domains + Cloud DNS

Demo

Google Cloud Networking Cloud Domains

Google Cloud Domains

- **Cloud Domains:** Primarily used for **Domain Registration and management**
- **Key Benefits**
 - Register **new domains**
 - Bills for purchasing/renewing domains will use the same **Cloud Billing account**
 - **Automatic renewal** of registered domains
 - Let's you manage **domain registrations per project**, not per user
 - **Supports DNSSEC** which protects your domains from spoofing and cache poisoning attacks
 - **Tightly integrated** with Google Cloud DNS (Domain Name system) for creating and managing DNS records

Registrations						
Filter Enter property name or value						
Status	Domain name	DNS	Renewal	Expires/renews on	Privacy protection	
<input checked="" type="checkbox"/>	kalyanreddydaida.com	Cloud DNS	Automatic	June 6, 2024	On	⋮

Google Cloud Domains

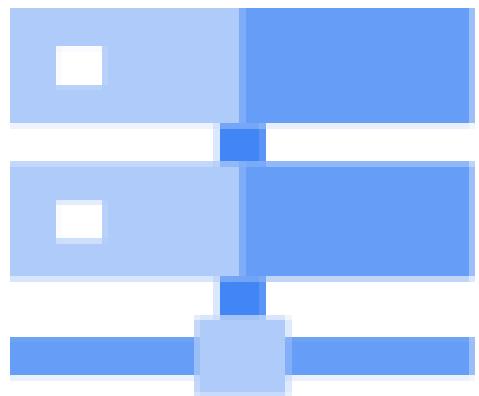

- **Important Note:** From September 7, 2023 onwards Squarespace acquired all domain registrations and related customer accounts from [Google Domains](#)
- Cloud Domains uses [Google Domains](#) as underlying domain registrar
- Now after squarespace acquisition, [Cloud Domains uses Squarespace Domains](#) as underlying registrar
- **How does this impact Cloud Domains in Google Cloud ?**
 - **Complete Faq:** <https://cloud.google.com/domains/docs/faq>
 - In a shorter note, [google supports Cloud Domains even](#) after this acquisition
 - **Following features in Cloud Domain will work as-is**
 - [Searching and registering](#) new domains
 - [Renewing](#) existing domains
 - Update your contact details and DNS settings
 - [Transfer](#) a registered domain to another registrar (GoDaddy, Namecheap, AWS Route53)
 - Transfer domain from [another registrar to Cloud Domain - NOT POSSIBLE](#)

Additional Reference: <https://cloud.google.com/domains/docs/deprecations/feature-deprecations>

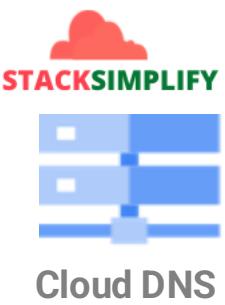

Demo

Google Cloud Networking Cloud DNS

Google Cloud DNS

- **Cloud DNS:** High-performance, resilient, global Domain Name System (DNS) service
- Cloud DNS translates requests for domain names like stacksimplify.com into IP addresses like 13.224.249.31

```
dkalyanreddy@cloudshell:~ (gcplearn9)$ nslookup stack simplify.com
Server: 169.254.169.254
Address: 169.254.169.254#53

Non-authoritative answer:
Name: stack simplify.com
Address: 13.224.249.31
Name: stack simplify.com
Address: 13.224.249.62
Name: stack simplify.com
Address: 13.224.249.81
Name: stack simplify.com
Address: 13.224.249.73
```

Google Cloud DNS - Terminology

- **DNS Zones:** It is a **container of DNS records** for the same DNS name suffix (Example suffix: stacksimplify.com)

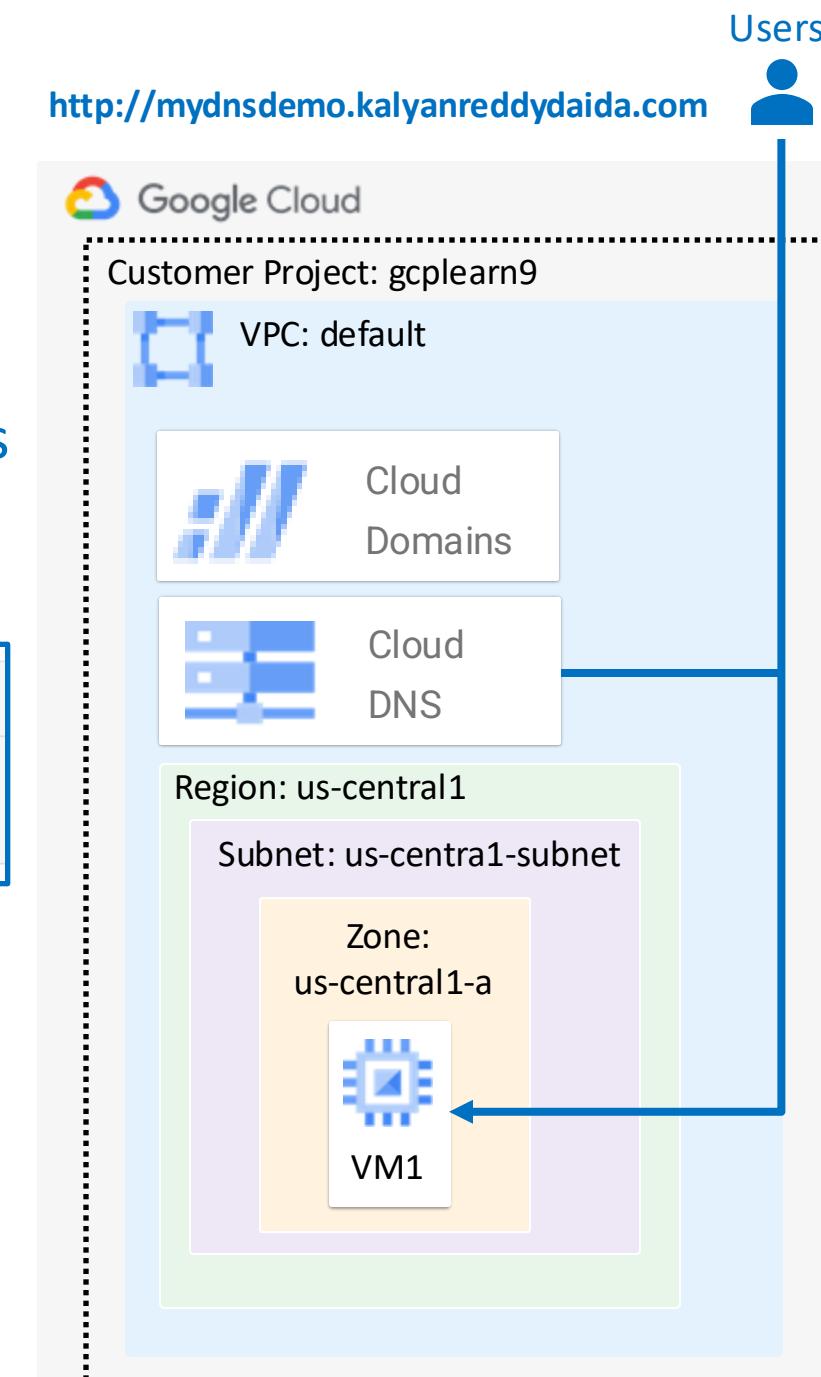

- **Public Zone**

- **Visible to the internet**
- Primarily used for **DNS management** of your **internet facing applications**
- **DNSSEC (DNS Security)** protects your domains from **spoofing and cache poisoning attacks**

Zone name ↑	DNS name	DNSSEC	Description	Zone type
kalyanreddydaida-com	kalyanreddydaida.com.	On	DNS zone for domain: kalyanreddydaida.com	Public

- **Private Zone**

- Contains DNS records that are **only visible internally** within your Google Cloud networks
- Easy to manage **internal DNS solution** for all our internal needs (For Internal applications, VM Instances etc)

Google Cloud DNS - Terminology

- **Record Sets:** actual DNS records
 - DNS Name to IP Address mapping
 - We have different record types, but primarily we use **Address record (A) type** which maps hostnames to IPv4 address

DNS Record Set

Create record set

DNS name: myapp1.kalyanreddydaida.com.

Resource record type: A

TTL *: 5

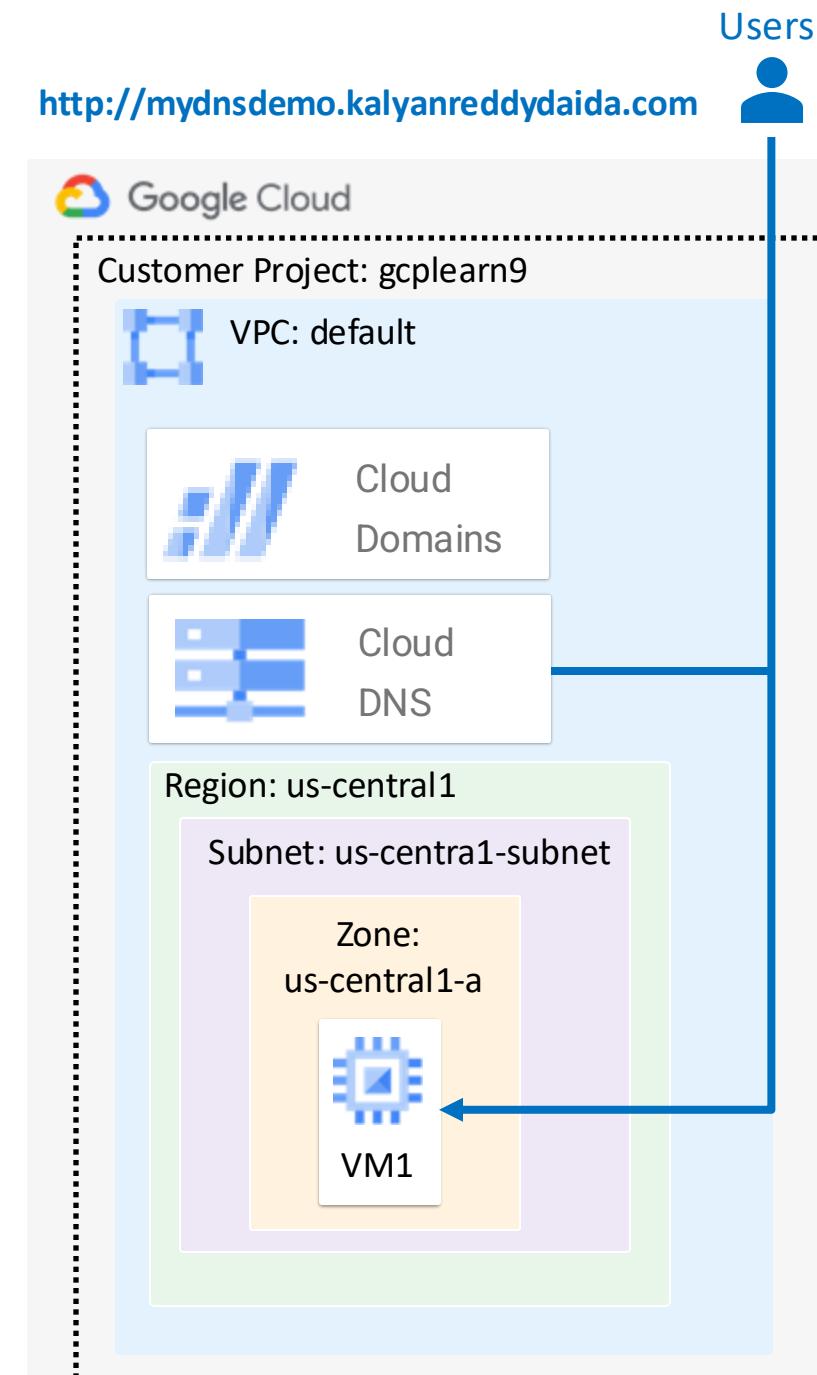

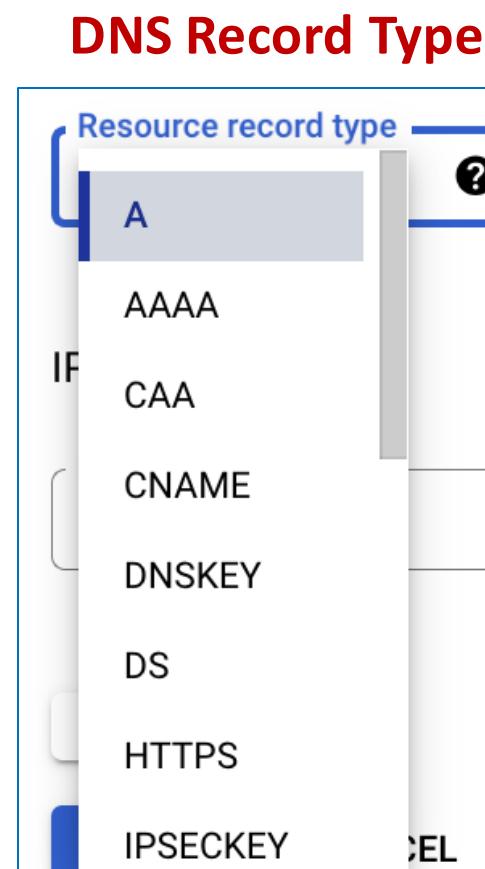

TTL unit: minutes

IPv4 Address *: 108.157.238.34

SELECT IP ADDRESS

+ ADD ITEM

CREATE CANCEL

https://cloud.google.com/dns/docs/records-overview#supported_dns_record_types

Google Cloud DNS - Features

- **Integration with Cloud IAM**

- Provides secure domains management with **full control and visibility** for domain resources

- **Integration with Cloud Logging**

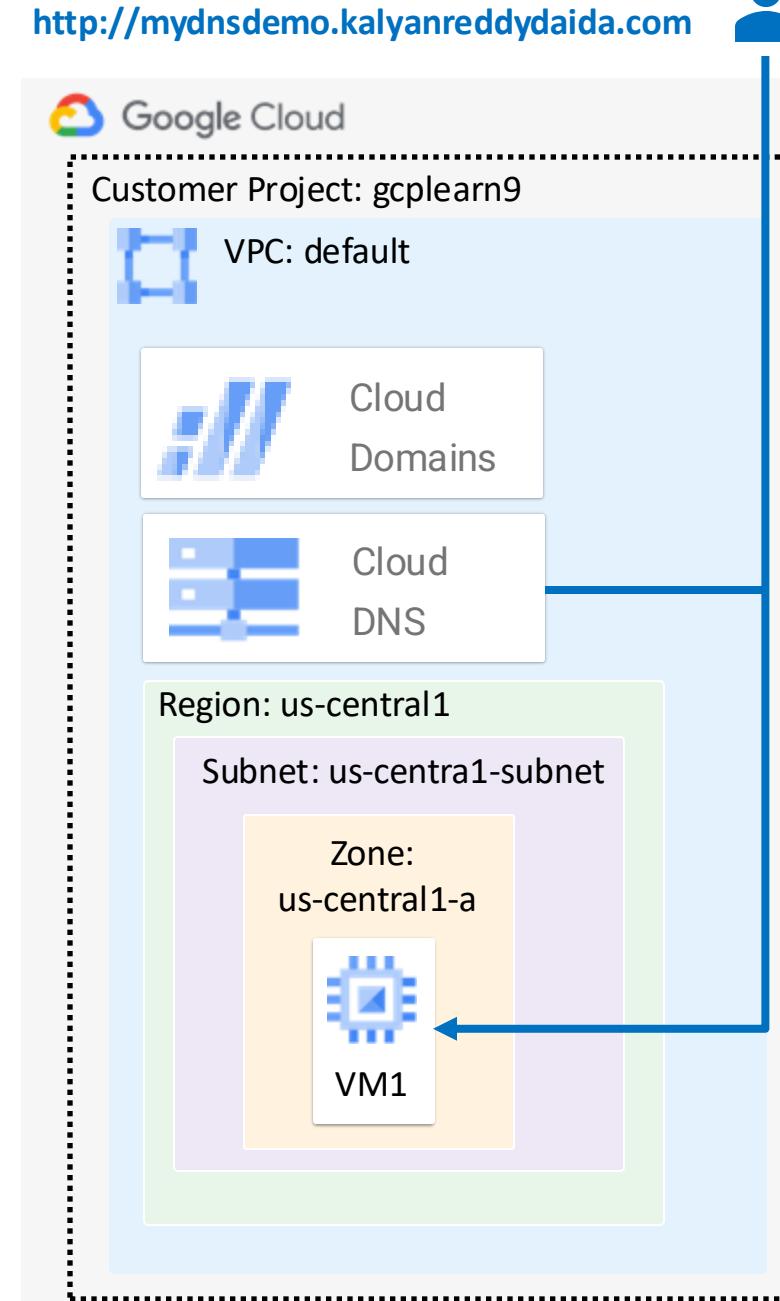

- Private DNS logs a record for **every DNS query** in Cloud Logging
- We can **view and export logs** to supported destinations

- **Fast anycast Nameservers**

- **Anycast:** Uses the **nearest nameserver to users** for DNS lookup and resolution
- Provides **very high availability** across globe and **low latency**

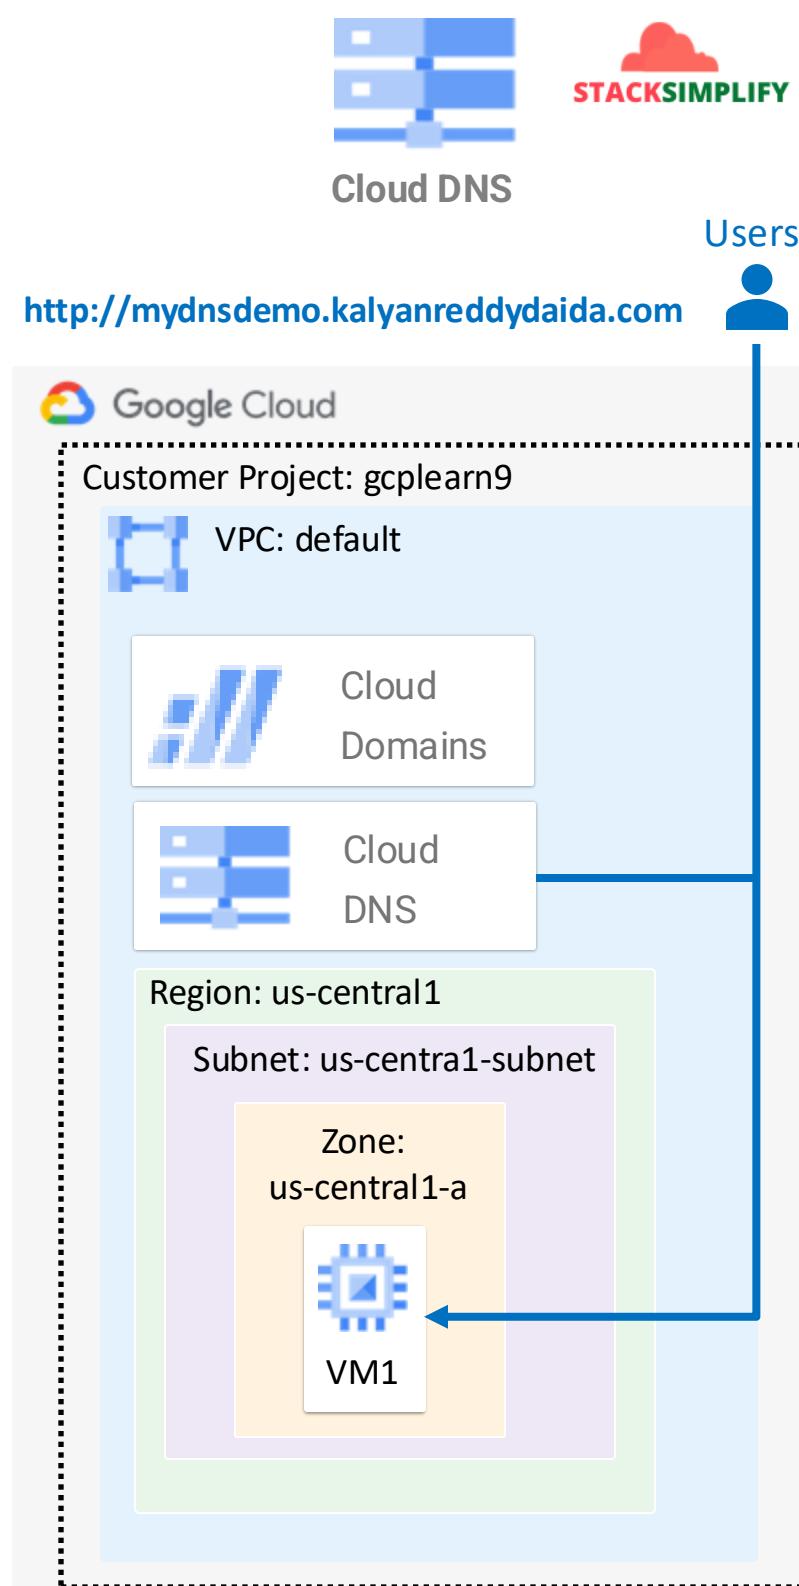

- **DNS registration and management**

- Cloud DNS is **tightly integrated** with Cloud Domains which takes care of DNS registration and management

Google Cloud DNS - Features

- **Container-native Cloud DNS**
 - Natively integrated with Google Kubernetes Engine (GKE)
 - Provides in-cluster Service DNS resolution
 - Provides high-throughput, scalable DNS resolution for every GKE node
- **DNS Peering**
 - Sharing DNS data
 - All or a portion of DNS namespace can be configured to be sent from one network to another
 - Will respect all DNS configurations defined in peered network
- **DNS Forwarding**
 - Primarily used for hybrid-cloud architecture
 - Forward DNS queries from Cloud DNS to on-premise DNS servers where actual DNS resolution takes place

Pre-requisite:
Registered Domain is
required to
implement this demo

Demo: Cloud SQL MySQL with Private Service Connection

C2

Added Variable related to MySQL DB version, updated in terraform.tfvars

C3-01

VPC, Subnet and Regional Proxy Subnet for Regional Load Balancer (Same as previous demos)

C3-02

NEW: Two resources(1. Reserve Private IP Range for PSC, 2. Private Service Connection Resource)

C3-03

No changes in VPC Outputs from previous demos

C4-01

Create Cloud SQL Database with private network enabled.

C4-02

Define private IP in Cloud SQL Outputs

C5

Create a VM Instance in VPC with mysql client installed to test private connection to Cloud SQL DB

Demo-26

Terraform

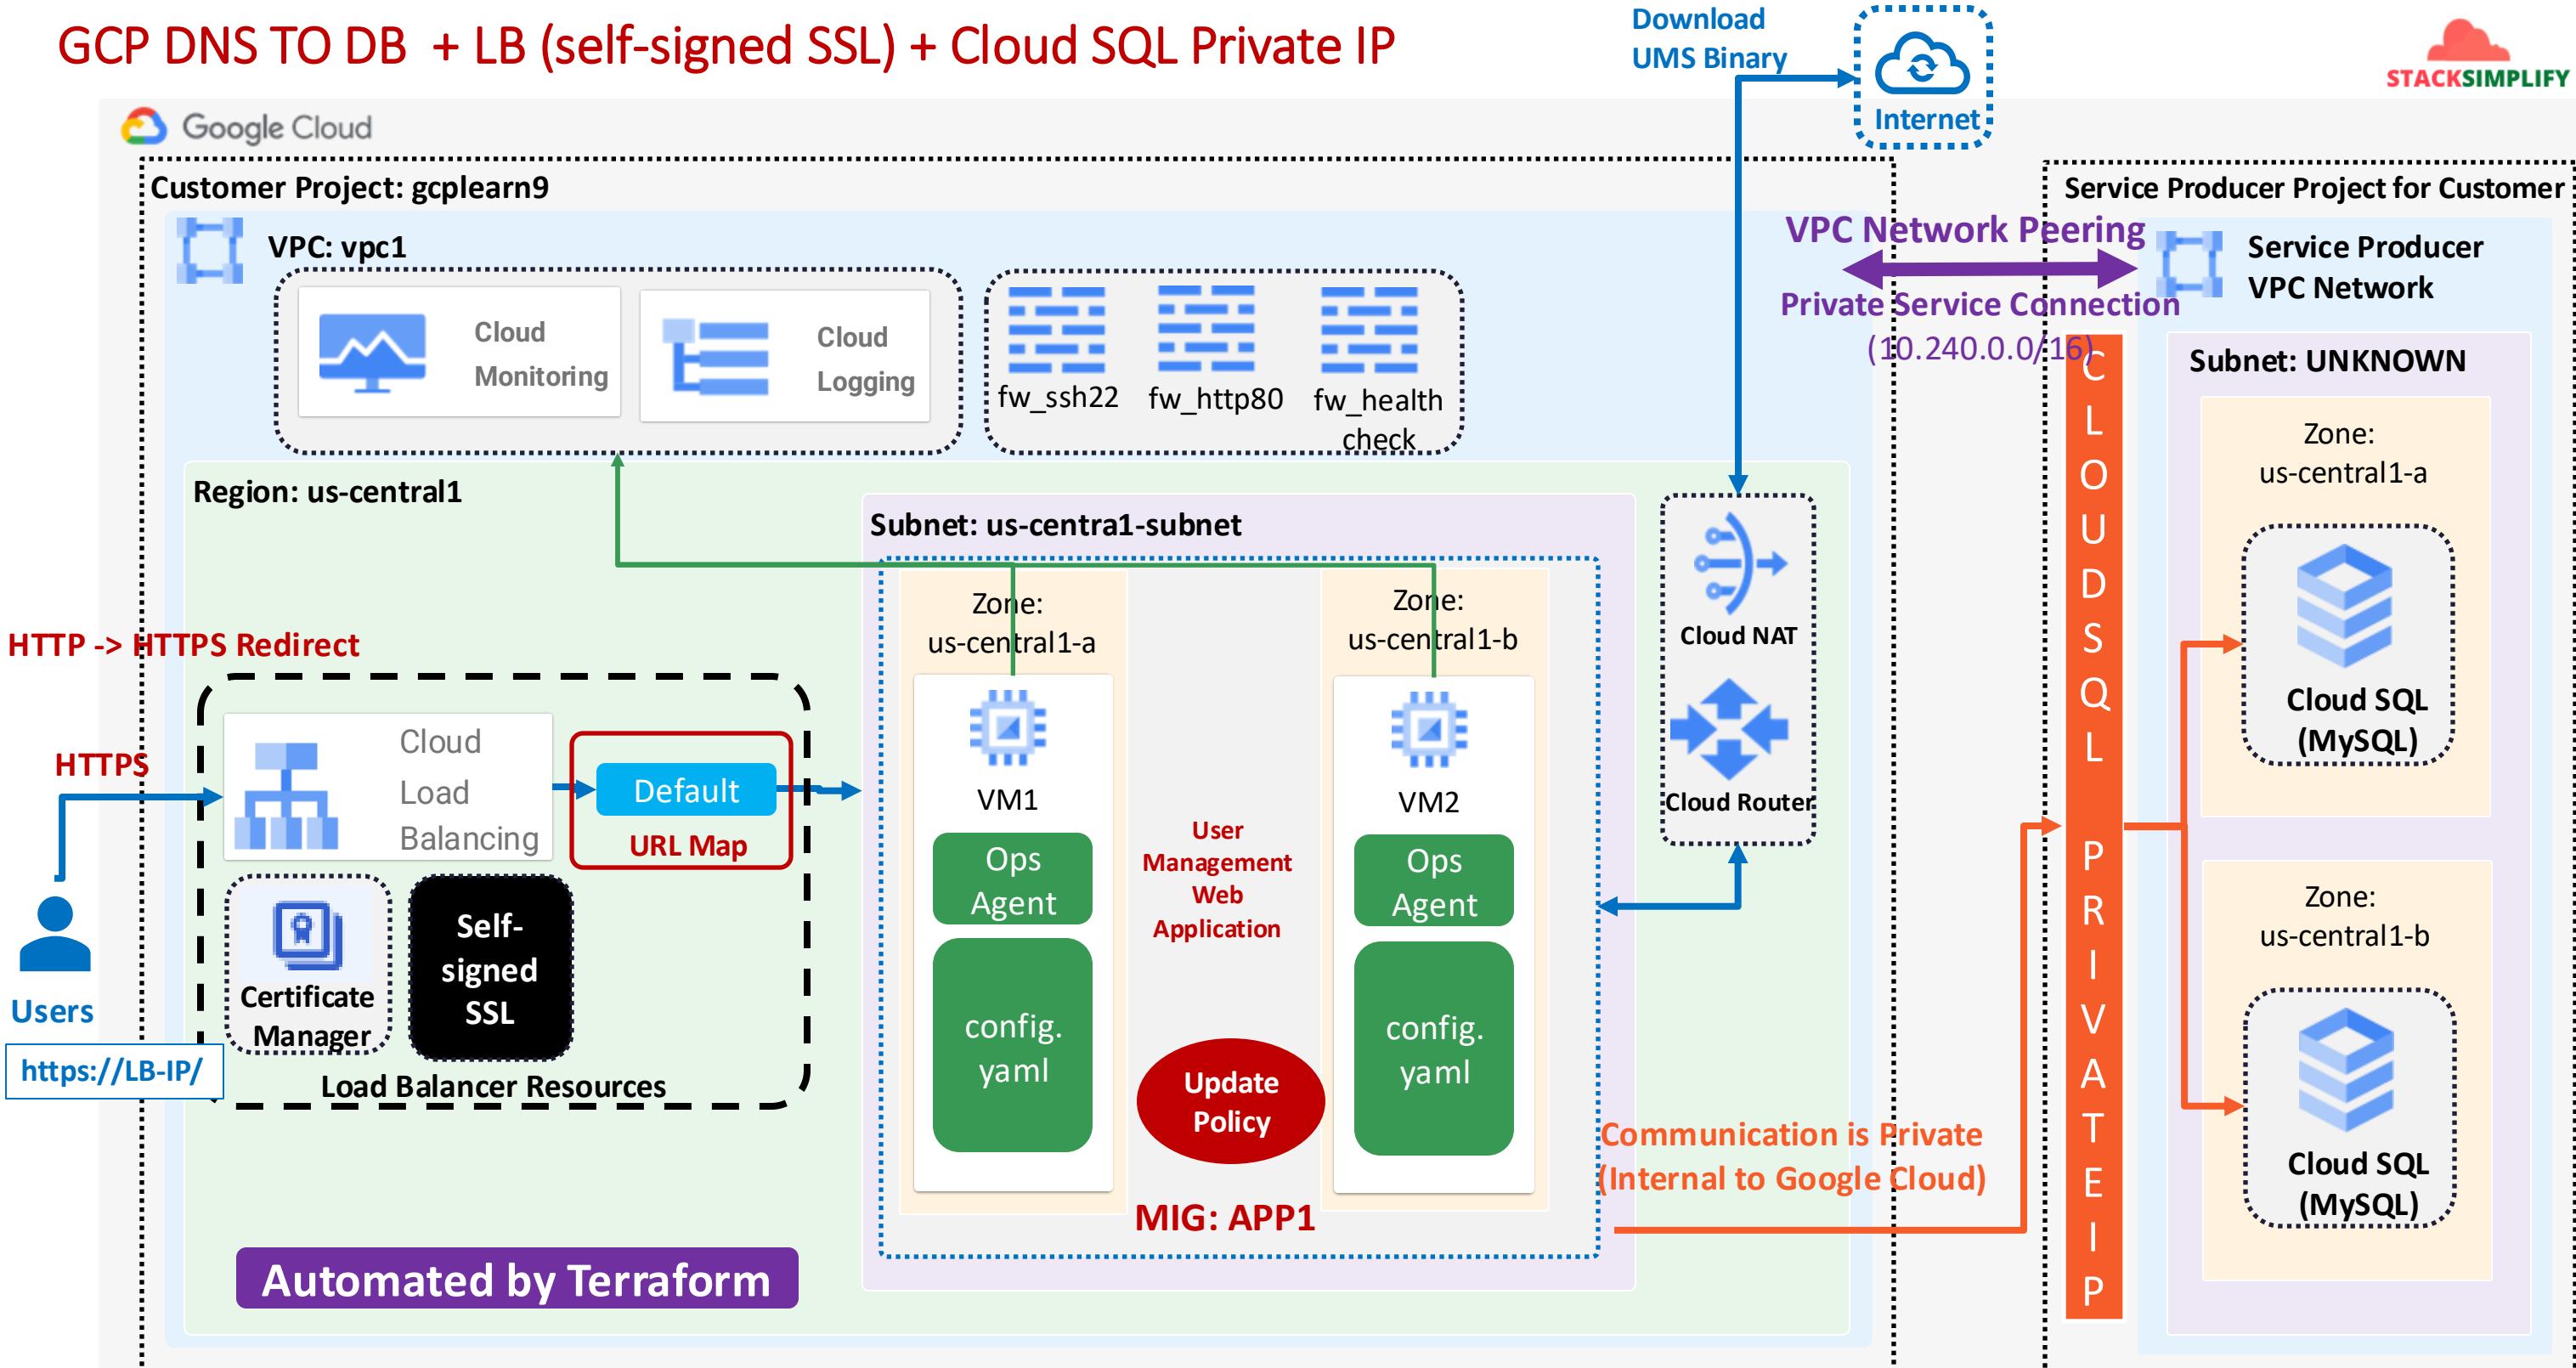

DNS to DB

Cloud SQL with Private Service Connection

Demo: Custom VPC + Regional MIG Private IP +
Regional Application Load Balancer HTTPS (Self-signed SSL) + Logging + Monitoring + Cloud SQL (Private IP)

GCP DNS TO DB + LB (self-signed SSL) + Cloud SQL Private IP

Terraform Modules

**Use pre-built Modules from Terraform
Registry**

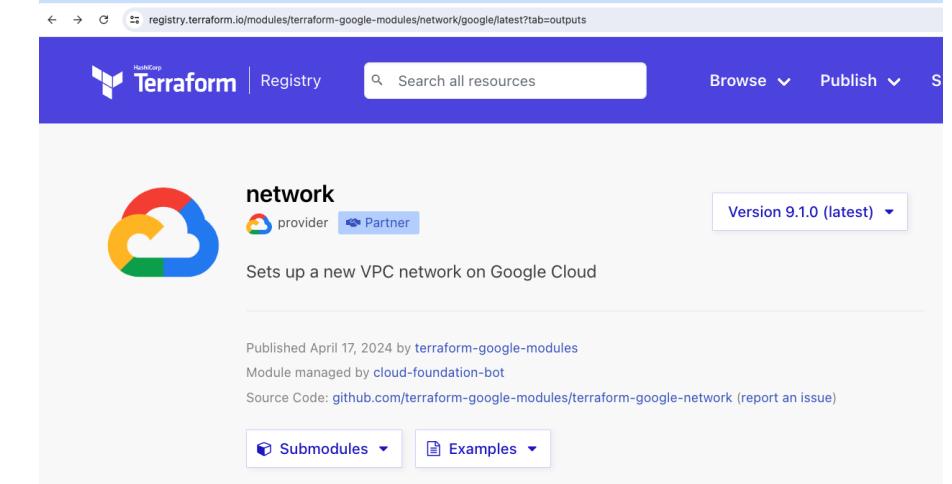

Demo: Custom VPC (Uses Terraform Module from Terraform Public Registry) + Firewall Rules + VM Instance

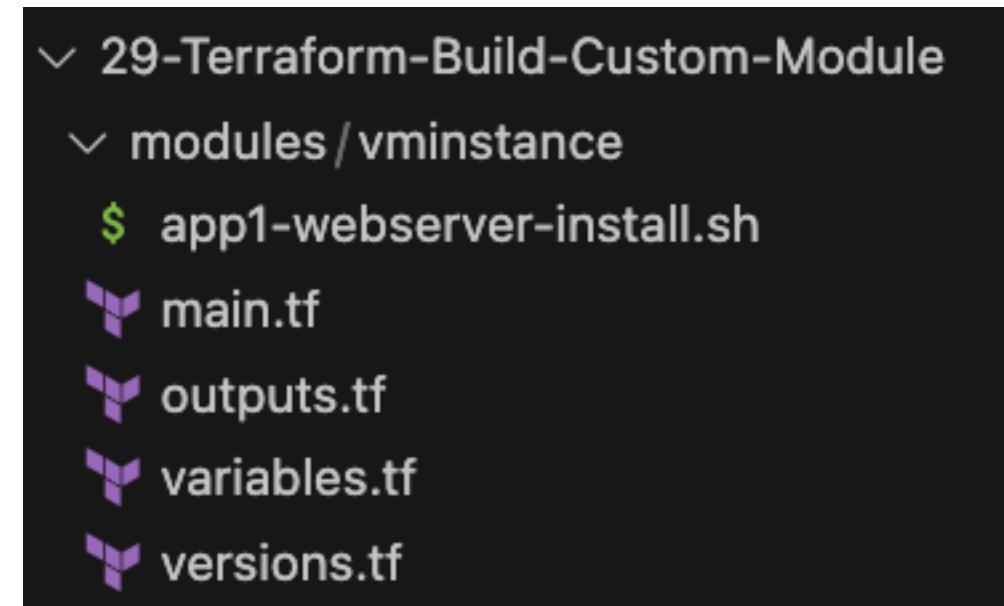

Terraform Modules

- A module consists of a **collection of .tf files** kept together in a directory.
- Modules are the main way to **package and reuse** resource configurations with Terraform.
- We can **compare modules to functions** in our standard programming languages (**define once and reuse wherever needed**)
- **Example:**
 - Define a VPC Module **once**, publish it to a Terraform registry
 - **Call** the VPC module wherever needed (reuse it)

Public Module on Terraform Registry

Custom Module

Terraform Modules

- **Root Module:** Every Terraform configuration has at least one module, known as its **root module**, which consists of the resources defined in the **.tf** files in the **main working directory**
- A Terraform module (usually the **root module** of a configuration) can call **other modules** to include their resources into the configuration.
- **Child Module:** A module that has been **called by another module** is often referred to as a child module.
- Child modules can be called **multiple times** within the **same** configuration, and **multiple configurations** can use the **same** child module.

Root Module

```
└─ terraform-manifests  
    └─ c1-versions.tf  
    └─ c2-variables.tf  
    └─ c3-locals.tf  
    └─ c4-vpc.tf  
    └─ c5-firewalls.tf  
    └─ c6-vminstance.tf  
    └─ c7-outputs.tf  
    └─ terraform.tfvars
```

Call VM Instance child module in Root Module

Child Module

```
└─ 29-Terraform-Build-Custom-Module  
    └─ modules/vminstance  
        $ app1-webserver-install.sh  
        └─ main.tf  
        └─ outputs.tf  
        └─ variables.tf  
        └─ versions.tf
```

Terraform Modules

- **Module Types**
 - **Local Modules (Local Paths)**
 - Accessible using [folder path](#) locally
 - Accessible locally [in that desktop](#) or for others via shared drives
 - **Public Modules**
 - Modules published to [Terraform Registry](#)
 - Publicly accessible to [anyone](#) ([Open source](#))
 - [Free to use](#), [use with caution](#), will contain continuous upgrades and might [break our current code](#)
 - If used, need to follow [strong version constraints](#) or [fixed module versions](#) to avoid major outages during upgrades
 - **Private Modules**
 - Modules developed and published to [private registry](#) in their respective organizations
 - Terraform Registry also supports [private registry concept](#)
 - Accessible only to that [respective organization users](#) (Highly secure, internal to that organization)

Terraform Modules

- **Module Storage and Access:** The module installer supports **installation from several different source types.**

- Local Paths
- Terraform Registry
- GitHub
- HTTP URLs
- S3 Buckets
- GCS Buckets
- and many more

Terraform Registry - Use Publicly Available Modules

The Terraform Registry hosts a broad collection of publicly available Terraform modules for configuring many kinds of common infrastructure.

Modules Demo 1

These modules are free to use, and Terraform can download them automatically if you specify the appropriate source and version in a module call block.

```
# Module: VPC
module "vpc" {
    source  = "terraform-google-modules/network/google"
    version = "~> 9.1"

    project_id    = var.gcp_project
    network_name = "${local.name}-vpc"
    routing_mode = "GLOBAL"
    subnets = [
        {
            subnet_name      = "${local.name}-${var.gcp_region1}-subnet"
            subnet_ip       = "10.128.0.0/20"
            subnet_region   = var.gcp_region1
        }
    ]
}
```

What are we going to learn?

Demo-31

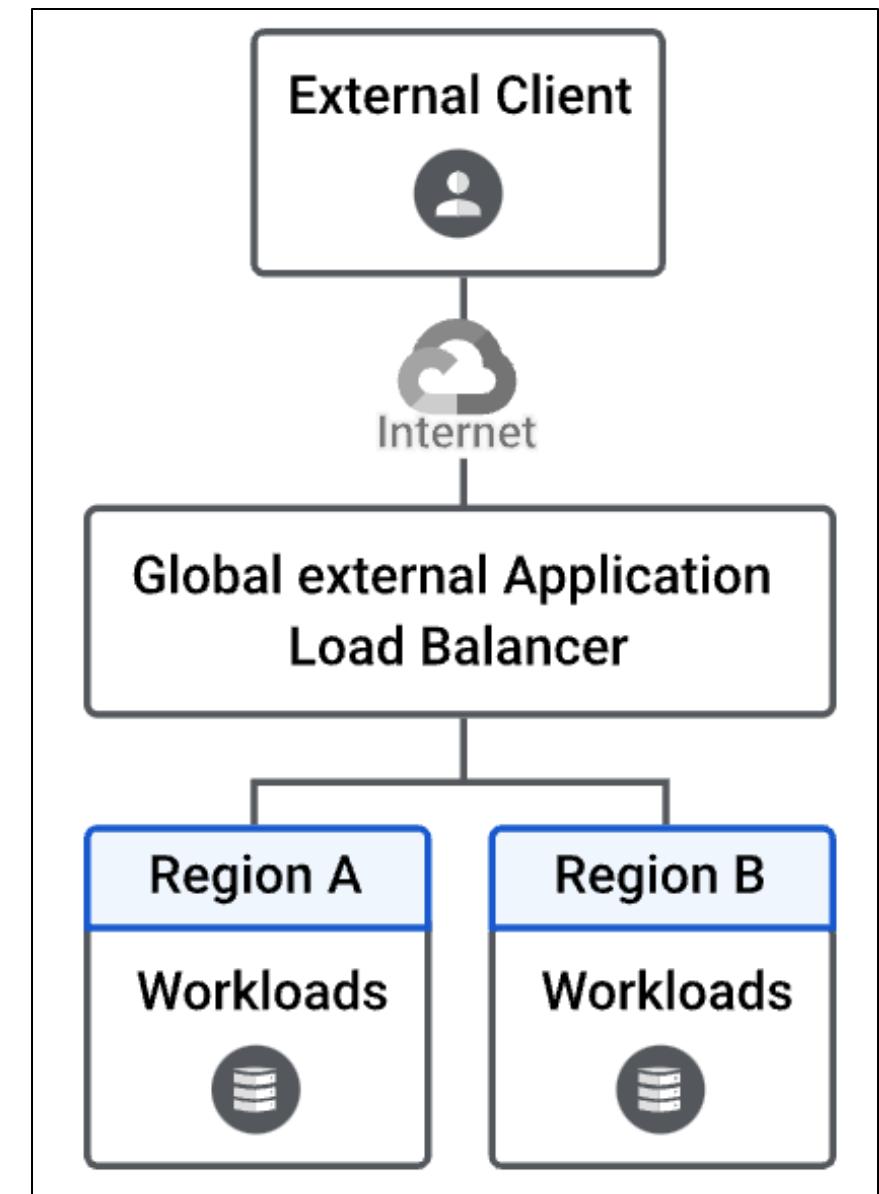

Terraform Global Application Load Balancer

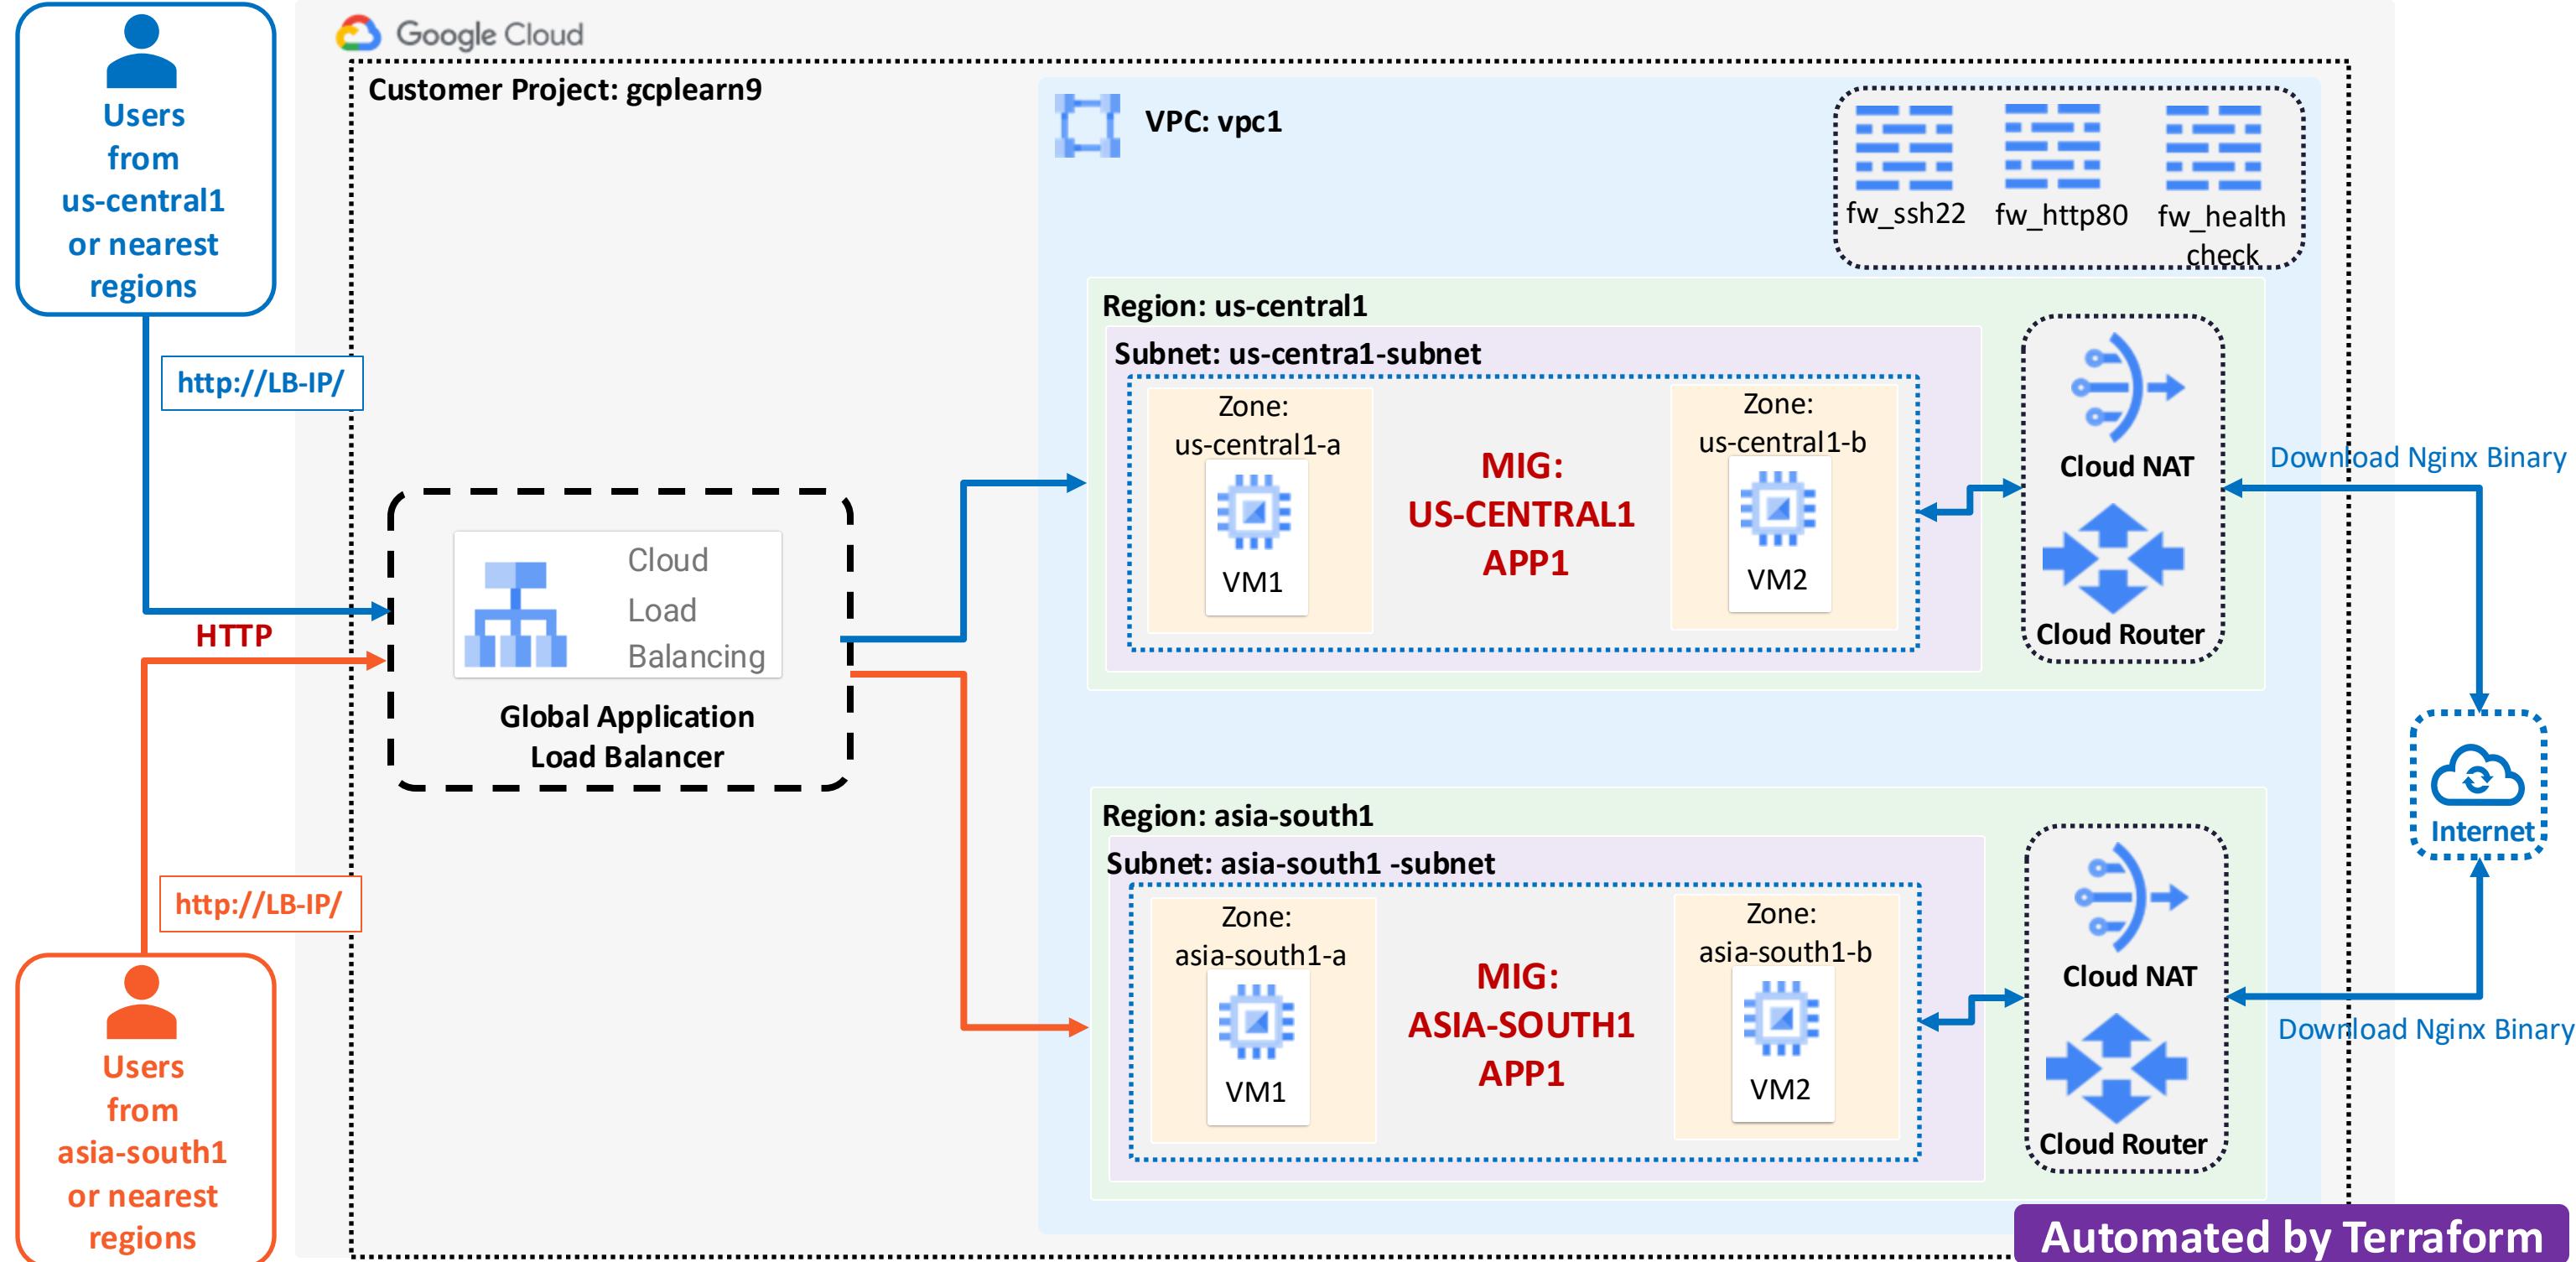

Demo: Custom VPC + Firewall Rules + Managed Instance Groups + Global Application Load Balancer

GCP Global Application Load Balancer

- **Global Application Load Balancer:** Load balances traffic **between regions** (multi-region load balancing)
- **Load Balancers Single anycast IP Address Feature**
 - Cross-region load balancing
 - Automatic **multi-region failover** (sends traffic to failover backends if primary backends are unhealthy)
 - Directs traffic to the **closest healthy** backend
- **Seamless Autoscaling (No config needed - Inbuilt):**
 - can scale as **your users and traffic grow**
 - It can **divert** traffic to other regions in the world that can take traffic (if one region is **overloaded**)
 - Autoscaling **does not require pre-warming**: you can scale from zero to full traffic in a **matter of seconds**.
 - In short, it is a **FULLY MANAGED SERVICE**
